The commonest of the vegetable acids not yet noticed are the following, oxalic acid being prefixed, as having a great analogy in properties with most of them, and as being of all the simplest in composition. These acids are all crystallizable, soluble in water, and, with one or two exceptions, sour to the taste. As a general rule the number of eqs. of oxygen exceeds that of hydrogen; and lastly, they are either monobasic or polybasic, as indicated by the number of eqs. of basic water in each:—

Oxalic acid....................	$C_4 O_6$, 2 HO	=	$C_4 H_2 O_8$
Fumaric and aconitic acids..	$C_4 HO_3$, HO	=	$C_4 H_2 O_4$
Gallic acid...	$C_7 HO_3$, 2 HO	=	$C_7 H_3 O_5$
Racemic and tartaric acids..	$C_8 H_4 O_{10}$, 2 HO	=	$C_8 H_6 O_{12}$
Malic acid.........	$C_8 H_4 O_8$, 2 HO	=	$C_8 H_6 O_{10}$
Citric acid.....................	$C_{12} H_5 O_{11}$, 3 HO	=	$C_{12} H_8 O_{14}$
Meconic acid....	$C_{14} HO_{11}$, 3 HO	=	$C_{14} H_4 O_{14}$
Tannic acid...........	$C_{18} H_5 O_9$, 3 HO	=	$C_{18} H_8 O_{12}$
Kinic acid.	$C_{14} H_{10} O_{10}$, 2 HO	=	$C_{14} H_{12} O_{12}$

Citric acid is found in the juice of the fruits of the orange or citron tribe, and in other acid fruits, as in the currant. Malic acid occurs in unripe fruits of the apple and pear tribe, especially in the fruit of the mountain ash or service tree. Tartaric acid is found in the grape as acid tartrate of potash, and racemic acid, which is isomeric with it, occurs only in the grapes of certain districts. Oxalic acid occurs in wood sorrel, *Oxalis acetosella*, and in the leaf stalks of rhubarb; also in other plants, as acid oxalate of potash; in lichens, Sedum, Sempervivum, &c., as oxalate of lime. Fumaric acid occurs in fumaria, aconitic acid in aconite and equisetum, meconic acid only in opium, the juice of the poppy, and kinic acid in cinchona bark. Tartaric acid and gallic acid, which are not sour, but astringent, are found in nutgalls, oak bark, and other astringent vegetables.

The frequency of polybasic, especially bibasic and tribasic acids, among vegetable acids, gives rise to many acid salts, such as the acid tartrate and acid oxalate of potash, and to many double salts, as the tartrate of potash and soda, and the tartrate of potash and antimony, Rochelle salt, and tartar emetic.

The neutral salts of vegetable acids with lime, oxide of lead, and oxide of silver, are usually insoluble, or if not, sparingly soluble. As there is a general analogy in composition, especially in regard to the excess of oxygen over hydrogen, so there is a general analogy in properties. But the astringent acids above named, and others like them, strike a deep blue or green colour, approaching to black, with the salts of iron; and kinic acid, in which the oxygen only equals the hydrogen, is a very weak acid.

Like all vegetable products, these acids, and all similar to them, are formed by the plant from carbonic acid and water, which contain the elements of all of them. But if we take as many eqs. of carbonic acid as the acid contains of carbon, and as many eqs. of water as it contains of hydrogen, which of course is the smallest quantity that can yield a given acid, we shall find that these materials always contain more oxygen than the acid formed from them. In other words, the plant in forming them deoxidizes carbonic acid and water, more or less, and thus oxygen, so removed, is given out as gas. Thus, oxalic acid, $C_4 H_2 O_8$, cannot be formed from less than 4 eqs. of carbonic acid and 2 of water, which are $C_4 H_2 O_{10}$, so that in this case 2 eqs. of oxygen are given out. All the other acids contain a smaller proportion of oxygen than oxalic acid, and therefore, in their formation, more oxygen is given out. Moreover, they may be formed either from carbonic acid and water, or from oxalic acid and water, or from any acid containing more oxygen than themselves; and it is probable that it is in this way by a succession of steps, that the plant produces all the vegetable acids, of which only the chief have been given above.

2. *Neutral and Mild Organic Compounds.*

Kinic acid, in which the hydrogen and oxygen are equal, leads to the next group, in all of which that is the case. They are few in number, but very abundant, widely distributed, and of great importance, as they constitute the chief mass of the vegetable kingdom. They are mild in character, and generally tasteless or sweet. They are as follows:—

Woody fibre or cellulose, *a*..................	$C_{12} H_8 O_8$
Woody fibre or cellulose, *b*..................	$C_{12} H_{10} O_{10}$
Starch	$C_{12} H_{10} O_{10}$
Cane sugar......	$C_{12} H_{11} O_{11}$
Gum...	$C_{12} H_{11} O_{11}$
Grape sugar, dry	$C_{12} H_{12} O_{12}$
Grape sugar, crystallized	$C_{12} H_{14} O_{14}$

In consequence of the equality between the oxygen and hydrogen in these compounds, they may be viewed as formed of carbon *plus* water; or, in other words, in forming them from carbonic acid and water, either directly or indirectly, that is, by successive steps, the plant gives out exactly as much oxygen as was contained in the carbonic acid from which they were derived. Hence their formation follows that of the acids, and they are probably formed in general from these acids, which would account for the uniform presence of the latter in vegetable juices.

Another fact, depending on the circumstance that they all contain 12 eqs. of carbon, and differ only in the amount of water, or its elements, is this: that all before grape sugar in the table may be converted, even artificially, into that kind of sugar. The conversion of starch into sugar constantly takes place in germination, as in malting, and that of both starch and woody fibre into sugar occurs in the ripening of fruits. In these processes, it is effected by the contact of a ferment. It consists in the addition of water or of its elements. The same result is obtained artificially by boiling them with diluted sulphuric acid, and also, in the case of starch, by adding an infusion of malt.

Woody fibre is insoluble in all solvents, and perfectly indifferent. Its most remarkable character is that of forming gun-cotton, or nitro-cellulose, when acted on by nitric acid. In that case, 2, 3, or more eqs. of nitric acid are taken up, while water is in some cases expelled, in others not. Gun-cotton is, in some instances at least, $C_{12} H_8 O_8, 4 NO_5$, so that if formed from cellulose *a*, 4 eqs. of nitric acid are taken up; if from cellulose *b*, 2 eqs. of water are given out at the same time. But there are several varieties of gun-cotton.

Woody fibre, by long digestion with alkalies or acids, is partially converted into a substance which, like starch, strikes a blue with iodine.

Starch consists of small grains, which are said to be hollow sacs, formed of an insoluble membrane, containing a soluble jelly. Others say that the grains are formed of successive layers of insoluble matter. Hot water causes them to swell and burst, allowing the contents to escape. The leading characters of starch are the becoming deep blue with iodine, and the being converted into sugar and rendered soluble by acids and by ferments. Before becoming sugar, it passes through an intermediate stage, in which it is dissolved as dextrine or gum.

Cane sugar is known by its crystals, and by being more soluble and sweeter than grape sugar. In contact with acids or a ferment, it becomes grape sugar, and then, but not before, it undergoes fermentation.

The action of the ferment appears to depend on its being in a state of decomposition, consequently of molecular motion; and this motion, communicated to the molecules or rather to the atoms of the sugar, suffices to destroy the existing equilibrium and produce a new one. Sugar undergoes several different fermentations, which we shall mention under grape sugar.

Gum is tasteless, viscid, soluble in water, insoluble in alcohol. By the action of nitric acid it is converted into mucic acid $C_{12} H_8 O_{14}, 2 HO$, and not, like sugar, into oxalic acid.

Grape sugar is distinguished from cane sugar by being less soluble and less sweet, and also by being easily decomposed into brown products by heating with diluted alkalies. It is the only kind of sugar which undergoes fermentation; all the others are first converted into grape sugar and then ferment.

When the ferment is yeast, or vegetable fibrine in a state of decomposition, the vinous fermentation takes place in solution of sugar. The juice of the grape and infusion of malt both contain sugar and fibrine, and only require to be exposed to the air. But if the air be carefully filtered, by being made to pass through tubes filled with cotton, no fermentation takes place. Hence, and because certain low organisms appear in fermenting liquids, it is probable that the change is induced in the ferment, not as was supposed by the oxygen of the air, but by the introduction of the minute spores or germs of these organisms, which find an appropriate soil in the fibrine. The vinous fermentation is expressed by the equation—

$$C_{12} H_{12} O_{12} = 4 CO_2 + 2 (C_4 H_6 O_2)$$

We have already stated that other allied fermentations take place, by which propylic, butylic, amylic, and other alcohols are formed along with common alcohol, but in small quantity. In these, water is probably also one of the products.

When caseine is the ferment, sugar, at the temperature of from 70° to 90°, is converted into lactic acid, or undergoes the lactic fermentation, which is this:—

$$\overbrace{C_{12} H_{12} O_{12}}^{\text{Sugar.}} = \overbrace{C_{12} H_{10} O_{10}, 2 HO}^{\text{Lactic acid.}}$$

With the same ferment at a rather higher temperature, lactic acid undergoes the butyric fermentation, especially if first neutralized. The change is—

$$\overbrace{C_{12} H_{12} O_{12}}^{\text{Lactic acid.}} = \overbrace{C_8 H_8 O_4}^{\text{Butyric acid.}} + 4 CO_2 + H_4$$

There is another fermentation not yet fully understood, but which occasionally accompanies the lactic fermentation. In this, sugar disappears, and we find only gum and mannite. Mannite is $C_6 H_7 O_6$, or $C_{12} H_{14} O_{12}$; and as gum is $C_{12} H_{11} O_{11}$, it is not easy to see where the mannite gets the excess of hydrogen. Probably some other substance is formed which has escaped notice as yet. It must contain an excess of oxygen, and is therefore probably an acid.

Sugar of milk has the same formula as dry grape sugar, and passes into that form by contact with acids and ferments.

In consequence of its being the only source of the compounds of ethyle, such as alcohol and ether, as well as of other alcohols and ethers, sugar is closely connected with the ethylic group of homologous compounds. We know nothing of its intimate constitution, except that, although resolved into alcohol and carbonic acid by fermentation, it does not seem to contain carbonic acid, nor consequently alcohol, ready formed. For by the action of permanganate of potash it is entirely converted into oxalic acid and water, which implies the addition to its elements of 18 eqs. of oxygen. Now, since carbonic acid is the ultimate product of the full oxidation of carbon in all organic compounds, it is hardly conceivable that oxalic acid, which is an inferior stage of oxidation, should be the sole product of the oxidation of carbon in a substance where any part of that carbon was already in the form of carbonic acid. We cannot, therefore, regard sugar as a compound of ethyle, and for the present must consider it as an appendix to the ethylic series, without knowing the precise relation between them.

Besides the kinds of sugar we have named, all of which pass into grape sugar, and in that form undergo fermentation, there appears to be a kind of sugar which is uncrystallizable, but which is probably rendered so by the presence of impurities. Molasses, or the syrupy uncrystallizable mother liquor from the cane juice is rendered uncrystallizable by the action of bases on the sugar during the evaporation, which produces two brown acids, glucic and melassic acids, the presence of which deprives a great part of the sugar of its power of crystallizing. This source of loss is now greatly diminished by carefully neutralizing with acid the lime used in clarifying the cane juice, and also by evaporating *in vacuo*, at a low temperature. The uncrystallizable sugar in molasses, and that in the residues of the cane, may be fermented, and yields the spirit called rum, which when new contains a trace of butyric acid, derived, no doubt, from a small portion of sugar having undergone the lactic and butyric fermentations. This butyric acid, on keeping, gradually combines with oxide of ethyle from a portion of alcohol, producing butyric ether, and the spirit thus acquires its very peculiar and fragrant odour, as well as the pleasant flavour of pine-apple. In Germany, rectified potato spirit, being first purified by rectification from all the oils which make the crude spirit so coarse in flavour, is converted into highly-flavoured rum by the addition of a very minute quantity of butyric ether artificially prepared. The presence of this ether in the pine-apple, to which it gives the flavour, is one of the few instances of the occurrence of a compound of ethyle as a natural product, and even here it derives its origin from sugar.

It is entirely in the form of sugar that all the starch in seeds, which usually contain it, becomes available in germination for the growth of the first stem and leaves; and it is in the same form that the starch in the food of man and animals enters the circulation, and is enabled to perform its proper function of supporting, by its slow oxidation, the animal heat. Here we see the extreme importance of the tendency in an organic substance like starch to undergo

isomeric transformation, for starch and grape sugar, differing only by 2 HO, may be held as isomeric. In the insoluble form of starch, this important element of food is stored up till required; and whether in germination or in digestion, for these processes are almost exactly the same, is rendered soluble and conveyed into the circulation or the juices of the animal or the plant. The reader will also observe that cellulose or woody fibre is most probably formed from sugar by another transformation of the same kind, in which water is separated.

3. Neutral Compounds; bitter, acrid, coloured, or yielding colours with ammonia.

In this group, which is a very numerous one, but formed of compounds generally limited to families, genera, or even species of plants, we include such bodies as the following. In their formation, the deoxidizing process has been carried a step farther than in the last group, for not only all the oxygen of the carbonic acid (or a quantity equal to it), but also a part of that of the water, has been given out. In the vegetative process. therefore, they are naturally produced after, and in all probability from, the substances of group 2.

Mannite	$C_6 H_7 O_6$, or $C_{12} H_{14} O_{12}$
Parietine	$C_{10} H_8 O_3$
Antiarine	$C_{14} H_{15} O_5$
Smilacine	$C_{15} H_{13} O_5$
Orcine	$C_{16} H_{11} O_7$
Quassine	$C_{20} H_{12} O_6$
Elaterine	$C_{20} H_{14} O_5$
Salicine	$C_{26} H_{18} O_{14}$
Pectine	$C_{28} H_{20} O_{26}$
Hæmatoxyline	$C_{40} H_{17} O_{13}$
Limonine	$C_{42} H_{25} O_{13}$
Cnicine	$C_{42} H_{37} O_{15}$
Phloridzine	$C_{42} H_{29} O_{24}$

We must observe that all of these formulæ are not absolutely ascertained, and that few of these substances have been as yet fully studied. But the general character of their formulæ is no doubt correct, and some, such as mannite, orcine, salicine, pectine, and phloridzine, are well known. As to their properties, mannite, as it is close to sugar in composition, so is it also in taste and mildness. Antiarine and elaterine are acrid and virulent poisons; quassine, salicine and phloridzine are bitter and febrifuge; pectine and pectic acid, a body closely allied to it, form the vegetable jelly of the juices of plants, such as the apple, currant, or carrot juices, and in fact are almost universally present. Hæmatoxyline is the red colouring principle of logwood, and is a type of a class hardly studied as yet. Orcine, which crystallizes beautifully, is a colourless principle found in some lichens, which, with ammonia, gives rise to the fine and permanent blue dye called archil, and is also a type of an interesting class of compounds recently investigated with great success by Schunck and others, particularly by Stenhouse. The rest are devoid of marked characters. This list is only a selection from a very large number of similar bodies, which, for the most part, have yet to be investigated, and on which, therefore, we need not dwell.

4. Oxygenated Volatile Oils, and Volatile Acids derived from them.

These we have already noticed under the head of the benzoic group. They are strongly marked in character, and in forming them the deoxidizing process has been carried still farther, as may be seen in the following list, which includes only the most important of them.

Oil of bitter almonds	$C_{14} H_6 O_2$
Benzoic acid	$C_{14} H_6 O_4$
Oil of spiraca	$C_{14} H_6 O_4$
Salicylic acid	$C_{14} H_6 O_6$
Oil of anise	$C_{16} H_8 O_4$
Anisic acid	$C_{16} H_8 O_6$
Cumarine	$C_{18} H_4 O_4$
Cumaric acid	$C_{18} H_4 O_6$
Oil of cinnamon	$C_{18} H_8 O_2$
Cinnamic acid	$C_{18} H_8 O_4$
Oil of cumine	$C_{20} H_{12} O_2$
Cuminic acid	$C_{20} H_{12} O_4$

It will be seen that in every case the oil, or in that of cumarine the resinoid crystalline body, differs from the related acid only by 2 eqs. of oxygen. These oils and resinoid bodies are moreover fragrant (cumarine is the odorous principle of the tonka bean), and both they and the acids. especially the latter, approach to resins in properties. as well as in composition.

5. Volatile Oily and Fatty Acids, with the oils and fats containing them.

As the growing plant pushes its deoxidizing agency still further, fixed oils and fats are produced, a class of compounds both important and abundant. We already know their proximate constituents, namely, the acids of the formic or acetic series (excepting only the two acids lowest in the scale, which are not oily) on the one hand, and on the other the basic oxide of lipyle, or of glyceryle, or glycerine. It is unnecessary to repeat the list of acids. but we shall quote a few for illustration, with the oxide of lipyle.

Oxide of lipyle (the base in fixed oils and fats)	$C_3 H_2 O$
Glycerine	$C_6 H_7 O_5$ $2 (C_3 H_2 O) + 3 HO$
Butyric acid	$C_8 H_8 O_4$
Capric acid	$C_{20} H_{20} O_4$
Myristic acid	$C_{28} H_{28} O_4$
Cetylic and palmitic acids	$C_{32} H_{32} O_4$
Margaric acid	$C_{34} H_{34} O_4$
Oleic acid	$C_{36} H_{34} O_4$
Stearic acid	$C_{36} H_{36} O_4$
Cerotic acid	$C_{54} H_{54} O_4$
Melissic acid	$C_{60} H_{60} O_4$

We have already explained that fixed oils and fats consist of such acids as these, combined with oxide of lipyle, which, when the oil is saponified by boiling with potash or soda, separates in the shape of glycerine. The only exceptions yet known are those of spermaceti, which is composed of cetylic acid, isomeric with palmitic acid, combined with oxide of cetyle, $C_{32} H_{33} O$, and wax, which consists partly of free cerotic acid, partly of palmitic acid combined with oxide of ceryle, $C_{54} A_{55} O$; and in some kinds of wax of melissic acid and oxide of melissyle, $C_{60} H_{61} O$. Drying oils, such as oil of linseed, of walnut, &c., consist of oxide of lipyle, united to a peculiar oleic acid, which rapidly absorbs oxygen and dries up into a resinous mass or varnish. The neutral fixed oils and fats, composed as we have stated, are produced by a very high degree of deoxidation, when compared with the preceding groups, and are therefore formed in an advanced stage of the vegetative process. Hence they abound in seeds. In some of them, as in wax, the oxygen is reduced to a small fraction. But, taken as a whole, the group may be represented as sugar or starch *minus* oxygen, for sugar is $C_{12} H_{12} O_{12}$, and the average composition of fixed oils and fats is represented by the proportion $C_{12} H_{12} O$, or $C_{12} H_{10} O$. Hence, if fats are formed in the animal body from starch or sugar, as it seems certain they are, it must be by a process of deoxidation. although the general nature of the animal vital process is that of oxidation.

6. Resins and Camphors.

This group is small in point of numbers, but very abundant and widely diffused. In it the oxygen is still farther diminished, as may be seen in the following list.

Many resins	$C_{10} H_7 O$
Camphor	$C_{10} H_8 O$
Borneo camphor	$C_{20} H_{16} O_2$
Many resins	$C_{20} H_{14} O_2$
Many acid resins	$C_{20} H_{15} O_2$

Among these bodies isomerism and polymerism prevail

to a great extent. The general character of the group is that they are very inflammable, fusible, insoluble in water, soluble in alcohol, frequently acid, but weak acids. Camphor is very volatile.

7. *Non-oxygenated Volatile Oils.*

In this group, which is both numerous and widely diffused, no oxygen is left. Isomerism and polymerism predominate among them, so that the following short list includes the most frequent proportions.

Oil of lemons and various others	$C_5\ H_4$
Oil of turpentine and various others	$C_{10}\ H_8$
Toluole	$C_{14}\ H_8$
Styrole or cinnamole	$C_{16}\ H_8$
Metastyrole or dracole	$C_{14}\ H_7$
Oil of juniper and others	$C_{15}\ H_{12}$
Cumole	$C_{18}\ H_{12}$
Cymole	$C_{20}\ H_{14}$

Most of the volatile or essential oils of this class have a strong aromatic smell, and are indeed the source of the smell of the plants in which they occur. They are usually obtained by distilling the plants, flowers, seeds, or exudations from trees, with water, with the vapour of which the oils readily pass over. Many of them occur in the exudation from trees, especially from many of the coniferæ, mixed with resins, constituting what is called turpentine or balsam. When this is distilled with water the resin is left behind, and in this way common resin is obtained along with oil of turpentine, from the turpentine of commerce. Balsam of copaiva and Canada balsam are turpentines which, containing more oil, are more fluid. These oils, exposed to air, absorb oxygen, and dry up into a resinous mass. Indeed most resins in composition are the oxides of the volatile oils which occur with them. Hence the use of oil of turpentine as a varnish and in oil painting. True varnishes, however, are solutions of resins in oil of turpentine, alcohol, naphtha, pyroxilic spirit, and other solvents.

The groups we have thus briefly sketched include all those vegetable compounds which consist of carbon, oxygen, and hydrogen only. But there are many and very important compounds which contain also nitrogen, and these we shall now endeavour briefly to indicate according to their natural affinities.

In order that these substances should be formed, the plant must be supplied with nitrogen, and this is done chiefly in the form of ammonia, or of nitric acid, both of which are conveyed to plants in the water which reaches their roots. In germination, however, there is another source of ammonia, namely, the decomposition of the albuminous or sanguigenous matter in the seed. Now it is remarkable that in germinating plants, before true leaves have been formed, and, what is the same thing, in etiolated plants, or those grown in the dark, the juice is found to contain a large proportion of a crystallizable nitrogenized compound, namely, malamide or asparagine. It would seem, therefore, as if this were the first nitrogenized body produced by the plant. Its origin is obvious. The plant first produces some acids, and among these malic acid. This meets with ammonia, and, water being separated, malamide is formed, or we may simply suppose it to be produced from carbonic acid, water, and ammonia. In the first case, malate of ammonia, $C_8 H_4 O_8, 2 NH_4 O$, losing 2 eqs. of water, yields malamide or asparagine, $C_8 H_{10} N_2 O_8$. In the second, 8 eqs. of carbonic acid, 4 of water, and 2 of ammonia, yield 1 eq. of malamide and 12 of oxygen; so that, whether malic acid be first formed, or malamide be directly produced, if it be formed from carbonic acid, ammonia, and water, it must be by deoxidation, as in all the preceding groups. This is no doubt the case in growing plants where it occurs, but in germination it may be formed, at least in part, by the decomposition of fibrine, albumen, or caseine. All other compounds of amide, or those of imide, or, in short, all derived from ammonia, are formed in growing plants in the same way, that is by deoxidation. There are thus formed several classes of compounds, neutral amides, such as asparagine or malamide, amygdaline, and similar bodies, of which white or colourless indigo, the source of the coloured indigo, is one; the volatile bases, which may be either amide, imide, or nitryle bases; and the fixed bases, which are either ammonium bases, or coupled compounds containing such bases. The formation of the volatile and fixed bases in the various forms of amide, imide, nitryle, and ammonium bases, we have already explained in their proper place. We shall here unite in one short list a few nitrogenized vegetable compounds of the kinds we have mentioned, all of which are produced in plants, either directly from carbonic acid, ammonia, and water, by deoxidation, or indirectly from ammonia acting on substances already formed by deoxidation from carbonic acid and water, as we have explained above with reference to malamide.

Asparagine or malamide		$C_8\ H_{10}\ N_2\ O_8$
White indigo		$C_{16}\ H_6\ N\ O_2$
Amygdaline		$C_{40}\ H_{27}\ N\ O_{22}$
Nicotine	volatile bases	$C_{10}\ H_8\ N$
Coneine	volatile bases	$C_{16}\ H_{16}\ N$
Morphine	fixed bases	$C_{35}\ H_{20}\ N\ O_6$
Quinine	fixed bases	$C_{20}\ H_{12}\ N\ O_2$
Strychnine	fixed bases	$C_{44}\ H_{22}\ N_2\ O_4$
Caffeine		$C_{16}\ H_{10}\ N_4\ O_4$

This list will give an idea of the composition of the greater number of crystallizable or volatile nitrogenized products found in plants. The number of fixed bases is very large, but they all resemble those quoted, which are the active principles of the plants in which they occur; morphine of opium, where it is associated with several other bases, codeine, papaverine, narcotine, thebaine, and narceine; quinine of cinchona bark, which also yields cinchonine and quinidine, and strychnine of nux vomica, which also contains brucine. Besides these, there are veratrine in veratrum, atropine in belladonna, aconitine in aconite, digitaline in digitalis, daturine in datura, colchicine in colchicum, and others of less interest. Nicotine and coneine, the active and very poisonous principles of tobacco and hemlock, are in all respects analogous to the volatile bases of the ethylic and benzoic series already noticed. Amygdaline is a bitter substance, peculiar to the bitter almond, which, in contact with water and the albuminous compound of the almond, undergoes a peculiar fermentation, and is resolved into several bodies not entirely known, but among them are hyduret of benzoyle and hydrocyanic acid, which together form the oil of bitter almonds of commerce.

White indigo is the substance present in the juice of indigofera, or at all events is produced by the action of ammonia on a substance there present, and as soon as it is formed attracts oxygen, and is converted into indigo, $C_{16} H_5 NO_2$, the white indigo losing 1 eq. of hydrogen. Indigo, when acted on by different reagents, yields a large number of very interesting products of decomposition. With 2 eqs. of oxygen it forms isatine, $C_{16} H_5 NO_4$, and this yields a whole series of substitution products, in which chlorine and bromine are substituted for its hydrogen, besides many derivatives from these. When heated with potash, isatine yields carbonate of potash, hydrogen, and aniline, or phenylamine, $C_{12} H_7 N$; so that the products of decomposition of indigo and its derivatives fall into the phenylic series. By the action of nitric acid, indigo is converted into two acids, according to the strength of the nitric acid. One of these belongs to the salicylic series, and is nitrosalicylic or indigotic acid, $C_{14} \left.\begin{matrix} H_5 \\ NO_4 \end{matrix}\right\} O_6$; the other is a yellow, intensely bitter, crystallizable acid, which forms with potash a salt nearly indissoluble. It has been called carbazotic, picric, nitropicric, and nitrophenisic acid; but it is simply hy-

drated oxide of phenyle, or carbolic acid, $C_{12}H_5O, HO$, in which 3 eqs. of hydrogen are replaced by 3 of nitrous acid, $C_{12}\left.\begin{matrix}H_2\\3\,NO_4\end{matrix}\right\} O, HO$. This again connects indigo with the phenylic series. The same acid, which might perhaps be best named trinitrocarbolic acid, is formed in many other cases of the oxidation of organic compounds by nitric acid, as, for example, from aloes, and from several resins. But we can only indicate the existence of the numerous derivatives of indigo in this place.

Caffeine is found, not only in coffee, but also in tea; and in Paraguay tea or guarana, used for the same purpose as tea or coffee. It has considerable analogy in composition, and also in the products of its decomposition, with certain animal products connected with uric acid, and it is probably in virtue of this that it acts as a kind of stimulant.

There are one or two volatile oils, such as those of garlic and assafetida, which contain sulphur. One, if not both of these, is sulphuret of allyle, C_6H_5, S; allyle being a radical either isomeric or identical with propionyle, the radical of propylic acid. Oil of mustard and oil of cochlearia are the sulphocyanide of allyle, C_6H_5S, C_2NS_2, and contain, therefore, both sulphur and nitrogen. In the formation of these oils in plants, carbonic acid, water, ammonia, and sulphuric acid are employed, and, as in all other cases, oxygen is given out.

There are various substances of no great importance which we have not specifically mentioned, but which all find their place in one or other of the groups of vegetable products we have named. Such are various colouring matters, and various volatile and crystallizable bodies, allied to the volatile oils.

But there remains one most important group of compounds formed by plants alone, and essential to the food of animals. This is the group of the albuminous or sanguigenous bodies, the only substances from which the animal system can form blood. These are three in number—albumen, fibrine, and caseine; and they are of all vegetable products the most complex, containing not only the five elements already mentioned (carbon, hydrogen, nitrogen, oxygen, and sulphur), but also—as essential constituents, without which, though in small proportion, they cannot even exist—mineral salts, especially phosphates. Moreover, the number of atoms in these compounds is far larger than in any we have mentioned, amounting, indeed, to hundreds. It is evident that one chief object of vegetation is the formation of these substances, and also that from their complexity they must be the last formed; and in fact they abound in the seeds, tubers, and other parts capable of reproducing the plant, and after the formation of which the plant dies down, either for a season or permanently. They are always accompanied by the two other classes of compounds, which with these constitute not only the first food of the young plant, but the food of animals, namely, starch, sugar, gum, or cellulose, on the one hand, or oils and fats on the other; these two constituting the respiratory part of animal food, as the three more complex products constitute the sanguigenous part of that food.

We may either conceive these compounds to be formed directly from carbonic acid, water, ammonia, and sulphuric acid, with the separation of oxygen; or, what is much more probable, we may suppose them formed from compounds already of a certain degree of complexity, such as sugar, with the aid of ammonia and sulphuric acid, or finally from sugar or some such substance, acted on by some nitrogenized compound, such as malamide. The precise steps of the process are unknown, but it is obvious that, whether formed directly or indirectly, they must be ultimately derived from the original food of plants—carbonic acid, water, ammonia, sulphuric acid, and the mineral salts derived from the soil—and that this cannot take place without the separation of a large amount of oxygen. The nearest approach we can make to the formulæ of these compounds is the following:—

Albumen and fibrine.....	$C_{216}H_{169}N_{27}S_2O_{68}$
Caseine.........	$C_{288}H_{228}N_{36}S_2O_{90}$

besides the phosphates. It is very difficult to ascertain with certainty such formulæ; but these, with respect to the proportions, represent the results of analysis; and as to the absolute number of atoms, we assume 2 eqs. of sulphur, because we find that these bodies contain sulphur in two different states, which implies at least 2 atoms.

These substances are essential to the growth of plants, as the vegetable cell, even if formed of cellulose alone, cannot be formed without the presence of one of these bodies. But in fact they also take part frequently in the formation of the cell wall, and the primordial utricle, or lining membrane of the cell, seems to consist chiefly of them.

Vegetable fibrine and albumen are isomeric; or, at least, the best analyses have not been able to show more difference between them than between different analyses of one of them. When dissolved in the vegetable juices, the fibrine coagulates spontaneously, the albumen when the liquid is boiled, and the caseine on the addition of an acid after the coagulation of the albumen, if all three or two of them be present together. In the solid form they are found, fibrine in the seeds of grasses and cerealia, albumen in those of nuts, almonds, and the kernels of stone fruit; and caseine in the seeds of the leguminosæ. The fibrine in grain is accompanied by starch and a little sugar, and in some cases also a little oil; the albumen is almost always associated with oil, as in almonds, walnuts, hazelnuts, and many other seeds; and in the seeds of leguminosæ the caseine is mixed chiefly with starch. In edible roots and tubers there is the same mixture. In the potato, fibrine and starch; in carrots, turnips, &c., fibrine, sugar and pectine; in pulpy fruits, fibrine, starch, sugar, and pectine, are the chief ingredients. In short, the vegetable cannot live and grow, and bear fertile seeds, without at the same time providing food for animals, not only in seeds, roots, and tubers, but also in leaves, leaf-stalks, leaf-buds, flower-buds; and, indeed, every part which is full of juice. And this leads us to consider the composition of the animal body.

But first we must remind the reader, that we have seen that plants live on carbonic acid, water, ammonia, sulphuric acid (in the form of sulphates), and phosphates, chlorides, alkalies, and other mineral matters—the three first compounds derived from the air, the rest from the soil. Secondly, that in germination, which takes place in the dark, oxygen is absorbed along with water, the albuminous matter in the seeds enters into decomposition, and becomes a ferment, by which means the starch is converted into sugar and dissolved, along with the greater part of the albumen, which is also rendered soluble by the fermentative action of the decomposed portion, while malamide appears, probably derived from the same source, and carbonic acid is given out. And thirdly, that as soon as the first leaves are formed, and light obtains access, the true, proper, vegetative process begins, in which, from the articles of their food above enumerated, plants produce acids, neutral substances, mild or acrid, or bitter or coloured, bases, oils and fats, resins, volatile oils and volatile acids; and finally, sanguigenous compounds, the formation of all of these being dependent on light, and being accompanied by the continual evolution of oxygen. Such is the nature of the vegetative process, carried on in virtue of the energy derived from the solar rays, and it is marked by three essential characters; the first is, that light is absolutely essential to it; the second is, that it is essentially a constructive process, in which the least complex compounds forming the food of plants are built up into more and more complex forms, till at last the sanguigenous bodies, the most complex of all, are produced; and the third, that it is a process of deoxidation of the food

of plants to a greater or less extent, and occasionally complete; but a deoxidation of a kind unknown in the laboratory, where we can only deprive bodies of oxygen by using others which seize and retain the oxygen, whereas the plant retains the carbon, hydrogen, and nitrogen, &c., and liberates the oxygen. The power required for this must be prodigiously great, and must far surpass that of our most energetic agencies; yet the vegetable cell effects it, without the help either of heat or of any other appliance. There can be no doubt that light is the source of this astonishing power; but, be this as it may, it is characteristic of vegetation.

Let us now turn to the animal system. We have stated that the food of animals is composed of two kinds of substance, the sanguigenous, and the respiratory. Both must be rendered soluble in order that they may enter the circulation, and this is effected in the process of digestion. It is remarkable, that this first animal process agrees with the first vegetable one, namely, with germination. In mastication, the food is divided and mixed with saliva, oxygen being added from the air, and being inclosed by the viscidity of the saliva. In the stomach, the gastric juice is added, which contains a little free acid, some albuminous matter dissolved, and the usual animal salts. The dissolved albuminous matter, acting as a ferment, at the temperature of the body, renders the sanguigenous portion of the food soluble, while either the same ferment, or, as is now believed, one peculiar to the saliva, converts the starch, if any be present, into sugar, so that it also is dissolved. The dissolved sanguigenous matter is gradually converted into blood, and from that fluid the various tissues are formed. The fibrine of flesh and the albumen of the blood are identical with vegetable fibrine and albumen; but the fibrine of the blood and the albumen of eggs are different. The two former, as we have already stated, are $C_{216} H_{169} N_{27} S_2 O_{68}$. Now, when one of them is employed to produce blood fibrine, or hematofibrine, which is $C_{298} H_{228} N_{40} S_2 O_{92}$, it may be in this manner that 2 eqs. albumen (or fibrine) with 2 eqs. of water are converted into 1 of hematofibrine, 1 of gelatine, $C_{82} H_{67} N_{13} O_{32}$, and 1 of choleic acid, one of the acids of bile, $C_{52} H_{45} NS_2 O_{14}$. Or it may be that 2 eqs. albumen and 4 of water yield 1 eq. hematofibrine, 1 gelatine, 1 cholic acid, the other acid of bile, $C_{52} H_{43} NO_{12}$, and 2 of sulphuric acid. Lastly, these two processes may be combined, so that—

$$\left.\begin{array}{c}\text{4 eqs. albumen}\\ \text{with}\\ \text{6 eqs. water}\end{array}\right\}\text{yield}\left\{\begin{array}{l}\text{2 eqs. hematofibrine.}\\ \text{2 eqs. gelatine.}\\ \text{1 eq. choleic acid.}\\ \text{1 eq. cholic acid.}\\ \text{2 eqs. sulphuric acid.}\end{array}\right.$$

By this it will be seen that the formation of blood fibrine is accompanied most probably by that of gelatine, necessary for membranes and bones, and that of the chief constituents of bile. Indeed, blood fibrine may be regarded as ordinary fibrine and albumen, half converted into gelatine and bile, for 1 eq. of it with 18 of water, may yield 3 of gelatine and 1 of choleic acid.

This example will illustrate the fact, that while the animal body cannot produce any sanguigenous body from food in which none of them is present, it can transform one into the other, as albumen into fibrine, fibrine into albumen, or both into caseine, or, as we have just seen, albumen or fibrine into hematofibrine; but that, where such changes are not isomeric transformations, they are a commencement of destruction, and their production, even if more complex, as is the case with hematofibrine, is not a pure case of construction as in the plant, but one in which with one more complex body others much less complex are produced. In the same way, when the food contains caseine, as milk does, and when hematofibrine is formed from caseine, it is accompanied by the production of chondrine, the substance of which cartilage, so necessary to the young animal, is formed. 1 eq. caseine with 10 of water may yield 1 of hematofibrine, and 1 of chondrine, $C_{72} H_{59} N_9 O_{32}$.

In this way, then, the animal body, if supplied with albumen, fibrine, or caseine, can produce from them, or any one of them, the materials necessary, in addition to themselves, for the formation of blood, muscular fibre, membranes, cartilage, bones, &c., even although these should be in part more complex than the food. But it is beyond the power of the animal body to produce any one of these substances from food which does not contain at least one of them, and for that food it is absolutely dependent on vegetables. Although we do not know the details, there can be no doubt that the formation of nervous matter or cerebral substance, is effected on the same principles. In this stage, water, as we have seen, is taken up, but oxygen is not required, nor is it given out. It is after the formation of blood and of the tissues, by some such changes as those we have specified, that the true vital process peculiar to animals begins. This process is exactly the reverse of the vegetative one; for while the latter, acting by deoxidation of the least complex among compounds which are its food, constructs or builds up those that are more and more complex, till it produces the most complex of all, that is, the food of animals, giving out during the whole succession of changes a large amount of oxygen; the former takes up, in respiration, a large amount of oxygen, acts by oxidation, and beginning with the most complex compounds, destroys them, and breaks them up into such as are less and less complex, ending at last with the very same substances as form the food of plants, and giving out all the time, in respiration, carbonic acid, in quantity equal, or very nearly so, to the oxygen absorbed, the difference of oxygen being given out as water.

These two great processes are exactly opposed, and, in point of fact, exactly balance each other, so that the air remains always of the same composition, although animals are constantly removing oxygen and replacing it by carbonic acid, because plants, on the other hand, are constantly removing carbonic acid, and replacing it with oxygen.

As to the products of the oxidation and destruction of the tissues in the animal body, they are very numerous, and only partially known. Such bodies as gelatine, chondrine, and the like, are among them, and it is to be observed that these products of destruction of the tissues, even when they approach in complexity the sanguigenous bodies, are not capable of forming blood. Thus gelatine alone can never support animal life, not being convertible into blood, as fibrine, albumen, and caseine are.

After such complex products of oxidation as gelatine and chondrine, there come probably a number of intermediate compounds, which, however, are as yet unknown. But at a certain stage in the oxidizing process bile is formed, which is composed of the two acids, choleic acid $C_{52} H_{45} NS_2 O_{14}$, and cholic acid $C_{52} H_{43} NO_{12}$, both combined with soda. We have already noticed these acids under the series of glycocine, which may be formed from cholic acid, while taurine, a compound containing all the sulphur of the bile, is obtained from choleic acid. In both acids, these substances are coupled with cholalic acid, $C_{48} H_{40} O_{10} = C_{48} H_{39} O_9, HO$.

Anhydrous cholalic acid........................	$C_{48} H_{39} O_9$
Anhydrous glycocine...........................	$C_4 H_4 NO_3$
Cholic acid....................................	$C_{52} H_{43} NO_{12}$
Anhydrous cholalic acid........................	$C_{48} H_{39} O_9$
Anhydrous taurine..............................	$C_4 H_6 NS_2 O_5$
Choleic acid...................................	$C_{52} H_{45} NS_2 O_{14}$

Cholalic acid, by boiling with water, is converted into a resinous acid, isomeric with the anhydrous cholalic acid, which is called choloidic acid; and when this is further boiled with acids, it yields a very insoluble resin, called dyslysine, which is choloidic acid *minus* 3 eqs. of water, or $C_{48} H_{36} O_6$.

Such are the chief products of bile. It is probable that all the sulphur of the tissues takes the form of choleic acid, that is, passes into the bile, before being expelled from the body as sulphuric acid by farther oxidation. The bile, which is mixed with the digested mass of food as it leaves the stomach, is apparently reabsorbed after producing some important effect in digestion, or in the conversion of the food into perfect chyle or blood, and being thus thrown into the circulation, it is destroyed by oxidation. We have already seen how the acids of bile may be formed from albumen or fibrine, along with hematofibrine, and also from the latter body by the addition of water; but they are also formed by oxidation. For example:—

$$\left.\begin{array}{l}\text{1 eq. albumen,}\\ \text{10 eqs. water, and}\\ \text{56 oxygen,}\end{array}\right\}\text{ may yield }\left\{\begin{array}{l}\text{6 eqs. choleic acid,}\\ \text{2 eqs. cholic acid,}\\ \text{12 eqs. urea,}\\ \text{36 eqs. carbonic acid.}\end{array}\right.$$

Or cholic acid may be formed, beside various other processes of oxidation, from chondrine and gelatine, as follows:

$$\left.\begin{array}{l}\text{1 eq. chondrine by}\\ \text{a fermentation,}\\ \text{probably}\end{array}\right\}\text{ may yield }\left\{\begin{array}{l}\text{1 eq. cholic acid,}\\ \text{2 eqs. uric acid,}\\ \text{8 eqs. water.}\end{array}\right.$$

$$\left.\begin{array}{l}\text{1 eq. gelatine, with}\\ \text{10 eqs. water,}\end{array}\right\}\text{ may yield }\left\{\begin{array}{l}\text{1 eq. cholic acid,}\\ \text{3 eqs. uric acid,}\\ \text{12 eqs. water.}\end{array}\right.$$

In all these three examples, it will be seen that the biliary products are accompanied by such as are urinary, urea, uric acid, and water, and also by carbonic acid. There are, no doubt, many other modes of decomposition and intermediate products, and some of these products we know, as for example, kreatine $C_8 H_{11} N_3 O_6$, and hippuric acid $C_{18} H_9 N O_6$, the former being found in the juice of muscle and in urine, the latter in urine. Now we can easily see how they may be formed, from gelatine for example, for—

$$\left.\begin{array}{l}\text{1 eq. gelatine, and}\\ \text{58 eqs. oxygen,}\end{array}\right\}\text{ may yield }\left\{\begin{array}{l}\text{3 eqs. kreatine,}\\ \text{2 eqs. hippuric acid,}\\ \text{12 eqs. water,}\\ \text{22 eqs. carbonic acid.}\end{array}\right.$$

Any of these substances, fully oxidized, will yield carbonic acid, ammonia, water, and, if sulphur be present, sulphuric acid. Thus—

$$\left.\begin{array}{l}\text{1 eq. of choleic acid, and}\\ \text{144 eqs. oxygen,}\end{array}\right\}\text{ yield }\left\{\begin{array}{l}\text{1 eq. ammonia,}\\ \text{2 eqs. sulphuric acid,}\\ \text{52 eqs. carbonic acid,}\\ \text{42 eqs. water.}\end{array}\right.$$

When uric acid is formed, it must, in warm blooded animals, be farther oxidized, so as to yield soluble compounds, or else by its insolubility it is deposited, producing calculous disease. In general, all the uric acid but a very small portion is thus oxidized, and the results are (uric acid $= C_{10} H_4 N_4 O_6$)—

$$\left.\begin{array}{l}\text{1 eq. uric acid,}\\ \text{3 eqs. water,}\\ \text{2 eqs. oxygen,}\end{array}\right\}\text{ yield }\left\{\begin{array}{l}\text{2 eqs. oxalic acid,}\\ \text{1 eq. urea,}\\ \text{1 eq. allantoine.}\end{array}\right.$$

or

$$\left.\begin{array}{l}\text{1 eq. uric acid,}\\ \text{8 eqs. water,}\\ \text{6 eqs. oxygen,}\end{array}\right\}\text{ yield }\left\{\begin{array}{l}\text{4 ammonia,}\\ \text{10 carbonic acid,}\end{array}\right\}\text{ or }\left\{\begin{array}{l}\text{2 urea,}\\ \text{4 water,}\\ \text{3 carbonic acid.}\end{array}\right.$$

It will be seen that the less complete oxidation of uric acid produces, besides urea, oxalic acid and allantoine. Oxalic acid does occur, and when it meets with lime is apt to form a calculus of the insoluble oxalate of lime. Allantoine is found in the allantoic fluid or fœtal urine, and in the urine of very young animals, in whom respiration, and consequently oxidation, is somewhat imperfect. But when the oxidation is complete, urea or ammonia, carbonic acid, and water, are the products.

Many more examples might be given of the mode in which the changes in the animal body may be supposed to be effected, and in some such modes they must be effected. But as we do not know all the different stages of the oxidation, nor all the products, we only give these representations as possible or probable, in regard to the details, although in principle certain; for all the facts we know prove that in the animal body every change is the result either of oxidation, more or less complete, or of a transformation with or without the addition of water, but never, as in plants, of deoxidation with liberation of oxygen. On the contrary, oxygen is constantly absorbed, carbonic acid constantly given out, and the complex substance of the tissues is constantly broken up into less and less complex compounds, till the final result is the food of plants.

It is in the very performance of their proper functions that the tissues are oxidized, and as fast as a portion of any tissue, being oxidized, is, while doing its work, broken up, the blood replaces it by a new portion derived from the food. At the same time the blood carries off the broken up or effete tissues, and out of them produces, according as the oxidation is more or less advanced, gelatine and the like, bile, juice of muscle, or urine. It is the blood which conveys to every part the oxygen necessary for the destruction of the tissues, that is, for the performance of their functions, which *is* their destruction. This is the reason why great efforts of any kind, muscular or otherwise, are attended with great waste of substance, and require an increased supply of food. It is the blood also, which, after it has carried the oxygen to act on the tissues, so as to enable them to perform their part, and in so doing to be destroyed, *pro tanto;* and after it has replaced the effete tissues which have, in becoming effete, fulfilled their office, by fresh material, also carries away not only the solid and liquid products of oxidation, but also the carbonic acid so largely formed, which it conveys to the lungs, and there exchanges for oxygen. But there is another source of carbonic acid besides the oxidation of the tissues. This is the oxidation or slow combustion of the respiratory food, of the sugar, &c., and the oils or fats, some of which are always present in food, as provided by Nature. And it is by this oxidation of the carbon and hydrogen of these matters as well as those of the tissues that the animal heat is kept up, without which none of the vital processes could be carried on. Now both the oxygen required for this purpose and the carbonic acid produced are carried to and fro by the blood, which at the same time has to perform three most essential functions, or rather four; first to enable the tissues, by oxidizing them, to perform their functions; secondly, to repair the waste of tissue; thirdly, to concoct or assist in concocting, out of the first products of oxidation, the various secretions and excretions; and lastly, to effect by the oxygen it carries the oxidation also of the respiratory food, or the production of animal heat, and to convey to the lungs the carbonic acid which is formed, and exchange it for oxygen.

The blood is admirably fitted for these purposes. It consists of water, holding in solution, besides salts, albumen and fibrine, and in this solution are suspended the red and white blood corpuscles. These seem to have much to do in the conveyance of the gases, which probably adhere to them. At all events, their colour changes from dark to bright red, according as the blood is loaded with carbonic acid (venous), or with oxygen (arterial). But that the blood may absorb so much carbonic acid, and yet give it out easily, it must be alkaline, and yet not too alkaline, which would retain the carbonic acid. This is accomplished by the presence of the peculiar phosphate of soda, tribasic with 2 eqs. of soda, which, acid in composition, is alkaline in character; namely $P O_5$, $2 Na O$, $H O$. It absorbs carbonic acid as well as carbonate of soda, and gives it off much more readily and completely. For another reason, the blood must be alkaline; for if it were acid, or even neutral, neither fibrine nor albumen could remain dissolved, nor could the necessary changes take place. Moreover, it must be phosphate of soda in the blood, and not that

of potash, for potash tends to form the salt $PO_5, KO, 2HO$, which is an acid salt. This very salt exists in the juice of muscle, which is almost in absolute contact with the blood, and in the gastric juice, but never in the blood, though the fluids which contain it are only separated from it by the most delicate possible membrane. The presence of these two fluids, blood and juice of muscle, one alkaline, the other neutral or slightly acid, in such close proximity, is probably connected with the existence of currents of electricity in the body, which have been demonstrated especially in muscular action. Two such fluids, with a porous solid between them, will always create an electric current.

It is obvious that for two chief reasons the supply of oxygen to the animal body must be abundant. It has to oxidize and destroy the tissues, that is, to enable them to perform their functions; and it also has to consume the respiratory food, and ensure the regular supply of animal heat. The effects of a deficient supply of oxygen are easily seen. The tissues being less thoroughly oxidized, the blood must become loaded with intermediate products. Among others, uric acid must occur, and give rise to calculous and gouty diseases. And this is the case. But deficiency of oxygen may arise from two causes; either from an absolute defect of oxygen, from diminished respiration, sedentary habits, which diminish respiration, and other analogous causes, or, what is more common, excess in food, whereby a full ordinary supply of oxygen becomes insufficient. This is the principal reason why excess in eating causes disease. Another cause may contribute to this, namely the deficiency of alkaline salts in the food, which is apt to occur if too much animal food and too little vegetable food be taken. The alkaline salts of vegetable acids are converted into carbonates in the system, and the presence of these greatly promotes oxidation; hence their absence or deficiency is injurious. For the same reasons, the strong wines of the south, which contain hardly any tartar, that is, acid tartrate of potash, are apt to cause calculus and gout, if habitually used; while on the Rhine, where wine is the only beverage, but the wines are weaker, and strongly charged with tartar, these diseases are unknown, save as imported.

When from any cause the supply of oxygen in proportion to the sanguigenous food is too small, the animal body possesses the singular power of obtaining a supply of oxygen from sugar or starch, which, by losing oxygen, are converted into fat. In this way the animal body can produce fat from sugar, like the plant, but the oxygen, instead of being given out, is employed to make up for the deficiency of that element. At the same time, as fat is formed along with it, the animal becomes fat. This explains why stall-fed animals fatten sooner than such as are outside; the former having a deficient supply of oxygen, that is, deficient respiration, compared with the latter; it also explains how the most fattening food is such as contains, with a certain proportion of sanguigenous matter, a large amount of starch or sugar. In this point, the practice of experienced feeders is entirely according to theory.

The food of animals and of man must contain a due proportion of sanguigenous and respiratory matter. For man, the best proportion is that found in grain and in milk, which are almost the only articles of food on which, alone, that is, on either of them without addition, life and health can be sustained. In them, the proportion is 1 part of sanguigenous matter to $4\frac{1}{2}$ or 5 of respiratory matter. Lean meat contains too little respiratory matter, although it contains a good deal of fat or oil diffused through it. Pease and beans and cheese are also too rich in sanguigenous matter, while potatoes and rice contain a great excess of respiratory food, which is the case also with very fat meat, such as bacon, &c. Hence, we usually add potatoes or rice to lean meat, and bacon or fat pork to pease and beans. Working men fed on potatoes require a very large supply of that food, so poor in sanguigenous matter, for it contains but 1 part of fibrine to 8, 10, or 11 of starch, to supply the daily waste of tissue, which starch cannot supply. With a large amount of potatoes they may thrive, but in that case much starch passes off unchanged in the excreta. On the other hand, when men are fed exclusively on flesh, they require a very large supply of it, as do carnivorous animals, because, besides supplying the waste of tissue, a large part has to be oxidized to yield the animal heat, for which it is far less fitted than starch. To burn off, or oxidize, so much sanguigenous matter requires a very large supply of oxygen, and this is the reason why carnivorous savages must lead a life of continual exertion, as they generally do in hunting for their food. For the same reason, carnivorous animals in confinement are always in motion except when asleep. The exercise increases the frequency and depth of respiration, and thus promotes oxidation. Lastly, the respiratory food is required, not merely to yield animal heat by its slow combustion, but also to yield fat by its deoxidation, which fat or oil assists in the formation of tissues from sanguigenous matter.

Such, in a very few words, are the general laws which regulate the food of animals. As to the excreta, they consist, for the most part, of the gases and vapours formed by oxidation, or carbonic acid and water, excreted by the lungs and skin, and ammonia, chiefly excreted in the form of salts in the urine; of the soluble salts which have served their purpose in the economy, or are the result of oxidation, as phosphates of potash, soda, and ammonia, sulphates, chlorides of potassium and sodium, &c.; of soluble organic excreta, as urea and kreatine, with traces, in man, of uric and hippuric acids, which, with the soluble salts and other less known substances, are excreted in the urine; and, finally, of the insoluble salts, as phosphates of lime, magnesia, and iron, along with any undissolved or insoluble matter in the food, as woody fibre, excess of starch, resinous matters, and certain fetid products of the oxidation of sanguigenous bodies which are also insoluble, but have not been fully studied, all of which insoluble matters form, with a certain amount of water, the solid or semisolid excreta. In cold-blooded animals, such as reptiles, where oxidation is very imperfect, there is no liquid urine; the whole excreta form one mass, which, in serpents for example, consists partly of undigested matters, bones, hair, feathers, and the like, but chiefly of a white salt, urate of ammonia. The same is true, to a great extent, of carnivorous birds, such as sea fowl, whose excreta consist of the bones of fishes and urate of ammonia. Exposed to the air, they became partly altered, the uric acid being in part converted into oxalic acid and other products, and the result is guano, which owes its value as a manure to the phosphates it contains, to the salts of ammonia, and to the uric acid, which is a source of ammonia when further decomposed.

We have seen that the animal process is the reverse of the vegetable one; that it begins where the other ends, with the sanguigenous and respiratory substances, and ends where the other begins, in the excreta, gaseous, liquid, and solid, which amount to carbonic acid, ammonia, water, sulphuric acid, or sulphates, phosphates, chlorides, &c., in short the very substances which are the food of plants. Urea, on being expelled in the urine, is soon transformed into carbonic acid and ammonia; for $C_2\,H_4\,N_2\,O_2 + 2\,HO = 2\,(NH_3,\,CO_2)$. This change takes place under the influence of a ferment, and the ferment in the urine is the mucus suspended in it; for if this be at once separated by filtration, the urea does not ferment.

We have noticed the composition of the best known among the constituents of the animal body, and the products of the various changes which occur during life. The various secretions are formed chiefly of water, with certain animal substances dissolved, generally in small quantity, and

 certain salts. Milk, which is important as a naturally prepared food, adapted more especially to the growth of the young animal, contains a considerable amount of caseine dissolved, which is identical with the caseine of pease, beans, and other leguminous plants. The respiratory food in milk consists of fat or oil, called butter, which we have already described under the head of the volatile oily acids of the acetic series, and of a peculiar form of sugar, called lactine or sugar of milk, the composition of which is $C_{12}\,H_{12}\,O_{12}$, the same as that of dry grape sugar, with which, however, it is only isomeric, not identical.

When milk is left to itself, the oil rises to the surface as cream. But soon after, the caseine enters into decomposition, becomes a ferment, and induces in the sugar the lactic fermentation, by which lactic acid is formed. This goes on till so much free acid is formed as checks the fermentation; which is, however, immediately renewed if the acid be neutralized by soda or chalk. The coagulation of the caseine instantly follows the formation of lactic acid, that is, as soon as the alkaline reaction proper to milk is neutralized, and it becomes distinctly acid. This is why milk when sour is found coagulated. The other method of coagulating milk, by means of rennet, an infusion of the lining membrane of the calf's stomach, depends on the dissolved sanguigenous matter in the rennet acting as a ferment, and coagulating the caseine rather by an action of contact, as it converts starch into sugar, than by the formation of lactic acid, for the coagulation by rennet is complete before the milk becomes perceptibly acid. The whey or serum, separated from the curd, contains all the sugar, various salts, especially phosphate of potash, and a small quantity of an albuminous matter not fully studied.

Cheese is the coagulated caseine, more or less perfectly separated from the whey, and containing more or less of the oil or butter, according as made from cream, from milk as drawn, or from skimmed milk, when only traces of oil are left. The different flavours and qualities of cheese also depend in part on the pastures, in part on the mode of manufacture followed in different places.

The gastric juice has been mentioned as resembling the juice of muscle, in being acid from the acid phosphate of potash, $P\,O_5$, $K\,O$, $2\,H\,O$. Its power of dissolving fibrine, albumen, &c., depends on its being acid, and on the presence of a ferment, or dissolved sanguigenous matter in a state of decomposition. We can imitate this solvent action out of the body by placing flesh in a solution of 1 part of hydrochloric acid in 1000 of water at the temperature of the body. A small part of the flesh, or of some of the membranes about it, is first dissolved, and by degrees the whole is softened and converted into chyme, in which the greater part of the fibrine is dissolved, and the oil suspended, giving it a milky aspect.

The pancreatic juice seems to have a special action in rendering fats and oils soluble, or at least capable of being absorbed. It is said to set free the acids which are more soluble than the fats themselves. Its composition is not perfectly known, but it resembles that of the saliva, which, as we have seen, is supposed to be the special agent in the conversion of starch into sugar. The bile and the urine we have already described. The latter is a solution of urea with salts, and certain little known products of the changes in the body, which are commonly grouped together as the extractive matter, besides traces of krealine, kreatinine, a base differing from kreatine in containing 4 eqs. of water less, hippuric acid, and uric acid. In the extractive matter of cow's urine there have been found a substance, taurylic acid, very analogous to, and probably homologous with, carbolic acid, also carbolic acid itself, and two other acids, both volatile and resembling carbolic acid. Carbolic acid is $C_{12}\,H_6\,O_2$, taurylic acid $C_{14}\,H_8\,O_2$, damaluric acid is $C_{14}\,H_{12}\,O_4$, and damalic acid, $C_{26}\,H_{24}\,O_4$. All these are, like carbolic acid, which occurs in tar, products of incomplete oxidation or combustion, as tar itself is; and their occurrence is a strong illustration in favour of the view which regards the body as a furnace, in which the food is the fuel, the carbonic acid, water, and ammonia are the products of complete combustion, and the soot and ashes combined are represented by the solid and liquid excreta.

The juce of muscle or of flesh is remarkable for being either neutral or acid, although in close proximity to the alkaline blood with only a thin and permeable membrane between them; also for containing potash where blood contains soda; and for the occurrence of kreatine in much greater quantity than in the urine. It also contains albumen, coagulable by heat.

Uric acid has been much studied, in reference chiefly to its products when oxidized. It yields a very large number of remarkable derivatives, but for the present these, although interesting to the chemist, do not admit of any application so important as to render it necessary to detail them here. We have stated what the most practically important results of its more or less complete oxidation are, and in the human body it is only a trace of it which, from its sparing solubility, can enter the urine, the rest being converted into urea chiefly with allantoine and oxalic acid in one case, and in the more frequent one, carbonic acid and water, or carbonic acid and ammonia.

Now that we have traced the two great processes of organized life, the vegetable and animal, and have seen how they are mutually related, and how they balance, and are dependent on each other, we can easily understand the principles which ought to regulate agriculture. Vegetation is entirely a chemical process, and subject therefore to chemical laws, although the vital force which modifies their action be beyond our reach. The plants, as we have shown, nay, the single cell, can effect changes which are beyond the power of the chemist, with all his appliances of heat, electricity, and chemical agents. But still these are chemical changes. If, then, vegetation be a chemical process, the foundation of a rational agriculture must be laid in chemistry.

Now the food of plants consists of two parts, the atmospheric and the terrestrial. The former is but little in our power, and therefore it is to the latter, that is, to the soil, that we must direct our attention.

We have already specified those elements which the plant derives from the soil, and which are fortunately present in almost every soil. They are sulphur, in the form of gypsum, phosphates of lime and magnesia, oxide of iron, carbonate of lime, potash, soda, silicic acid, and in some cases iodides and fluorides. But some of the most essential, especially the phosphates, are often present in so small a proportion as not to suffice for the purposes of agriculture.

The first principle that may be laid down is this, that to render a soil generally fertile, all the mineral substances which are really essential to the crops must be present, and in sufficient quantity. The absence of one essential ingredient renders the others, however abundant, totally useless. No plant can grow in a soil destitute of phosphates, or of sulphates, or of alkalies. Some plants may grow, indeed, in the absence of one important mineral element, as, for example, of potash, but only on condition that some other analogous substance, such as soda in some cases, and lime in others, replaces it. There is no means of remedying the absence of phosphates or of sulphates, because nothing else can replace them.

The next point to be noticed is, that the crops raised for food in agriculture exhaust the soil of certain constituents to a far greater extent then any natural vegetation can do. In all cultivated plants, the edible part, whether seeds, roots, or leaves, has been brought to a most unnatural development, for the sake of the food they yield. Now, a great

part, and the most valuable part of that food consists of sanguigenous matter; and this, as we have already stated, cannot exist without a certain amount of phosphates of lime and magnesia. There is no such thing known as albumen, fibrine, or caseine, without phosphates. Now of all the useful constituents of the soil, the phosphates are the least abundant, so that in many cases a cultivated crop or two exhausts the soil of all its available phosphates. The same thing is true of any other constituent required for the cultivated crop and not very abundant in the soil.

The next principle is this, that if the soil by nature can produce an average cultivated crop, this degree of fertility can only be kept up in one way, that is, by restoring to the soil exactly what we have removed of mineral matter in the crop. For this is another difference between natural vegetation and cultivated crops, that in the latter case a great part of the crop, and that by far the richest in mineral matter, especially in phosphates, is exported or abstracted from the land. This is the principle on which the use of manures depends, for manures are nothing but different means of restoring to the soil what we have extracted from it.

The next remark we would make is, that common or farm-yard manure is evidently, from its origin, a most excellent form of manure; for, consisting of straw which is part of the crop, and of the solid and liquid excreta of animals fed on another part of it, the latter, as we have explained, represent the ashes of that part of the crop on which the animals have fed. But the ashes of any crop are exactly the mineral substances which it required and extracted from the soil, and in the very proportions required; so that the ashes of any crop must be the best manure for another crop of the same, provided the first crop was a good one.

Unfortunately only a part of the crop is consumed on the spot and converted into manure, and therefore the farmer must have recourse to other modes of restoring what has been removed, or of supplying what may be deficient.

The most natural quarter to which he can apply is the excreta of large town populations, both of men and of animals, which have consumed that part of his crops which was exported. But hitherto this invaluable manure has been, for the most part, carefully washed down into the sea, and thus lost for ever to the land, except in so far as a part of it is recovered, at a most disproportionate cost, in the shape of sea-ware, and still more of guano. For the town manure, conveyed into the sea, there promotes the growth of sea plants of all kinds; on these small animals feed; on these again fish; on these larger fish, and on these perhaps sea-fowl, whose excreta, after ages of exposure, are imported as the most precious manure, while at the same moment we are recklessly casting away the very best manure for our crops, being the ashes or mineral part of these crops, contained in the excreta of towns.

Another manure, imported also at great cost, and like guano very likely to fail us ere long, is bones or bone dust. As we have already said of guano, in speaking of uric acid, that its value chiefly depends on the phosphates it contains, so is the value of bones measured by the phosphates. But the animals whose bones we purchase feed on our crops, or on others similar to ours, and every particle of phosphate in them has been extracted from the soil in these crops. In bones, therefore, we are only restoring, as in guano, at great cost, a part of what we have removed from the soil. And what we gain in bones is lost to the countries exporting them.

In short, every particle of manure ought to be carefully preserved, whether on the farm, or in large cities where it is now thrown away to the value of millions annually. Experience and observation have taught this truth long ago to the Chinese, who do not allow the smallest portion of that to be wasted which has been extracted from the soil; and yet probably they have no theory, no science to guide them. When shall we, who can see why this ought to be done, act with the same common sense as the Chinese have long exhibited?

Besides the phosphates, for the sake of which farm-yard manure, guano, and bone-dust are chiefly valued, there are other substances which must be restored to the soil. Sulphate of lime or gypsum is fortunately present in considerable proportion in most soils, but where it is deficient one crop may exhaust the soil of it. It is easily obtained, being a common rock, or mineral.

The alkalies, although almost always present in considerable proportion, are yet apt to fail, because it is only that portion which is soluble that can avail the plant. Now the potash is all derived from felspar, but felspar is quite insoluble, and it is only in so far as it is decomposed that it yields its potash. This decomposition is effected by exposure to air, and one of the chief advantages of ploughing and fallow is to facilitate the decomposition of the disintegrated felspar, which is the chief ingredient of clay soils, and forms part of all soils. Some kinds of felspar are much more slowly decomposed than others, and but a small quantity of potash is available at any one time when such kinds prevail. One crop may entirely exhaust the available potash, and the most liberal supply of phosphates and sulphates will be of little use unless the supply of potash is at the same time attended to. Hence the use of nitre as a manure, or at least one use of it, and of carbonate or sulphate of potash.

But there is another expedient, which acts by increasing the supply of potash. This is the use of lime. The true action of lime is not, as has been supposed, to destroy the organic matter remaining in the soil, but to assist in the decomposition of felspar, which is rapidly decomposed when in contact with quicklime and water. This is the reason why lime is more advantageous in stiff clay soils, which are soils full of felspar.

The burning of very stiff clay also promotes the subsequent action of the weather on the felspar.

In grain crops and in grass much silica is required for the straw. Now silica abounds in all soils, except perhaps some chalky soils. But silica can only enter the plant in the form of alkaline silicates, and therefore the decomposition of felspar which directly supplies silicate of potash is doubly important.

A question naturally arises here. What is the value of organic matter in the soil or in manures. Now it is at once evident that it cannot be essential to the growth of plants as some have stated, that the soil, or the manure, or both, should contain organic matters, or mould, which is organic matter half decayed. For the first plants must have grown in a soil without a trace of mould. Moreover, direct experiment has often proved that plants will thrive in a purely mineral soil, provided it contain all the mineral elements essential to the growth of the plant. In that case the plant obtains from the air exclusively, through water, the carbonic acid and ammonia from which it obtains the whole of its carbon and nitrogen.

But fertile soils do contain mould and other organic matters, as do also most manures. Are these of no use? —far from it. The advantages are these. The slow and constant decay, or oxidation of the mould, &c., gives rise to a constant supply of carbonic acid in the soil itself. A part of this is conveyed to the plant dissolved in water along with the carbonic acid of the air. Another part of it being also dissolved by the water of the soil, dissolves out of the soil carbonates and phosphates of lime, magnesia, and iron, and is the chief means of introducing these into the juice of the plant. And in both ways, in supplying carbon and in supplying mineral matter, this carbonic acid derived from the carbonaceous matter in the soil greatly accelerates the growth of the plants, and very much shortens the period required for them to reach maturity. This, in our northern latitudes, is a matter of the last importance. But even in-

dependent of this advantage in point of time, it is probable that a very large part of the phosphates, &c. enters the plant by virtue of the carbonic acid formed in the soil.

The advantages derived from the presence of ammonia in the manure, or of substances yielding it either in the manure or in the soil, is analogous. The plant, if supplied with all the necessary mineral matter, will, indeed, obtain the ammonia, without which it cannot avail itself of these from the atmosphere. But the proportion of ammonia in the air is so small, that a long time in our climate is required for this, and any addition to the supply of ammonia has the effect of enabling the plant to attain maturity sooner.

While, therefore, the plant is not absolutely dependent on the presence of organic matter in the soil or in the manure, there is a decided advantage in its presence there.

Those who have employed a special manure, such as gypsum, or bone-dust, or guano, with good effect, are apt to make sure of the same result on repeating the application. But they are often completely disappointed; for the effect of the first application, say that of gypsum, to a soil deficient in it, has been to produce a heavy crop for which gypsum alone was wanting. But it must be remembered that the heavier the crop the more probable is it that the raising of it has exhausted the soil for the time of some one of the other essential elements, perhaps of the phosphates, in which case a second application of gypsum is dead loss.

Again, it often happens that when a special manure has been found very successful, the same farmer or his neighbour immediately applies it to the first field he has in hand, and perhaps derives no benefit whatever from it. The reason is, that a special manure can only do good where the soil is deficient in the substance supplied by that manure. Gypsum will produce astonishing effects on soils destitute of that substance, but containing all the other elements of fertility; but if added to a soil which, like very many, contains already far more gypsum than is required for many crops, it is merely thrown away.

The advantage of rotation of crops is very obvious. Both the phosphates, which are usually minutely diffused in rocks, and silicate of potash, so essential to grain crops, are only rendered gradually available by the gradual disintegration and decomposition of the felspar and other rocks. If, then, by one crop, one mineral element has been more exhausted than another, let us suppose this to be the case with the available or soluble silicate of potash, a grain crop having been raised, a repetition of the same crop would fail for want of a sufficient supply of this material. But a green crop, requiring hardly any, if any, silicate of potash, would find sufficient phosphates, gypsum, lime, and alkalies, and would allow the action of the weather to go on gradually rendering available a new supply of the silicate. This example will illustrate the principle. In the application of it, as of the other principles we have laid down, experience is the best guide, because there are still very many points, the theory or principle of which is quite obscure, but in regard to which the experienced and intelligent farmer acts with confidence. We cannot attempt to do more here than briefly to indicate the general principles of the application of chemistry to agriculture. The agricultural reader must be referred to works expressly written on this most important subject, such as those of Davy, Liebig, Johnston, and others.

We have now brought to a conclusion the brief and imperfect sketch which we proposed to give of organic chemistry. Our limited space made it absolutely necessary to condense and select the matter presented to the reader. Moreover, the science is in a state of transition, and of very rapid progress, which renders the task doubly difficult. We have endeavoured to lay down, as much as possible, leading principles, and to avoid mere details. We have not even dedicated a section to the destructive distillation of organic substances; but most of the products will be found alluded to under various heads, as those of the hydurets of the ethylic and acetic radicals, the volatile bases of the ethylic and benzoic series, acetic acid, &c. &c.

We can only trust that the difficulty of condensing so large and varied a multitude of facts and their relations into so small a space will excuse the many imperfections of the execution. (W. G.)

CHEMNITZ, or CHEMNITIUS, MARTIN (1522–1589), a famous Lutheran divine, the disciple of Melancthon, was born at Britzen in Brandenburg. He was employed in several important negotiations by the Lutheran princes, and was professor at Brunswick for 30 years. He wrote *Examen Concilii Tridentini*, Frankf. 1585, 4 vols. fol. and 4to; *A Treatise on Indulgences*, 8vo, Geneva, 1599; *Harmonia Evangelica*, 1600, and *Theologiæ Jesuitarum præcipua capita*, Rochelle, 1589.

CHEMNITZ, a town of Saxony, in the circle of Zwickau, stands in a beautiful and well-watered valley on the river Chemnitz, an affluent of the Mulde, 35 miles W.S.W. of Dresden. It is the first manufacturing town in Saxony. In point of population it ranks third, having (1849) 30,753 inhabitants, of whom 30,036 are Lutherans. The cotton goods, especially stockings, for which it is chiefly celebrated, and to which it owes its present prosperity, rival even those of England in quality and cheapness; one factory, the largest in Saxony, having 18,600 spindles. It is also celebrated for the making of spinning machinery. Chemnitz is a place of considerable trade, exporting a great part of its industrial products to the United States; and has manufactures of linens, bleaching and dye works, and tanneries. A railway connects it with Riesa, and thence with Leipzig, Dresden, Berlin, &c. The town is neat, clean, and well built, containing many fine edifices, among which may be mentioned the great church, town-house, and cloth-hall. Chemnitz was for four centuries a free imperial city.

CHEMOSH, or CHAMOSH, the name of a national god of the Moabites and of the Ammonites, whose worship was introduced among the Israelites by Solomon (1 Kings xi. 7). No etymology of the name which has been proposed, and no attempt which has been made to identify this god with others whose attributes are better known, are sufficiently plausible to deserve particular notice. Jerome's notion that Chemosh is the same as Baal Peor has no historical foundation; and the only theory which rests on any probability is that which assumes a resemblance between Chemosh and Arabian idolatry (cf. Beyer, *Addit. ad Selden.* p. 322; Pocock, *Specimen*, p. 307). Jewish tradition affirms that he was worshipped under the symbol of a black star; and Maimonides states that his worshippers went bareheaded, and abstained from the use of garments sewn with the needle. The black star, the connection with Arabian idolatry, and the fact that Chemosh is coupled with Moloch, favour the theory that he had some analogy with the planet Saturn.

CHEMOSIS, an inflammation of the eyes, causing the cornea to redden and swell, so as to impede vision.

CHENAUB, the ancient Acesines, a river of the Punjaub, which has its source in Lat. 32. 48., Long. 77. 27., in the British district of Lahoul, S. of Ladakh, or Middle Thibet. Its course is first north-westerly to Kishtawar, in the dominions of Gholab Singh, the present ruler of Cashmere; thence it proceeds S.W. to Riasi, where it leaves the mountains and enters the plain of the Punjaub. At Akmur, 50 miles below this point, it becomes navigable—at least for timber rafts. From Akmur it continues a south-west-

erly course for 250 miles to its confluence with the Jhelum or Behut, a little above the ferry of Trimo, in Lat. 31. 12., Long. 72. 12. About 50 miles below the confluence the Chenaub forms a junction with the Ravee, and subsequently with the Ghara, the united stream being thence designated the Punjnud (five rivers), a name which it bears to its fall into the Indus. The length of course of the Chenaub to its confluence with the Ghara measures about 765 miles.

CHENIER, Marie Joseph de, was the son of Louis Chenier, the author of *Recherches Historiques sur les Maures*, and *Révolutions de l'Empire Ottoman*. He was born in 1764 at Constantinople, where his father was French consul-general. At an early period of life he entered the army; but soon afterwards retired to Paris, and devoted himself to literary pursuits. His first production, a tragedy, was acted in 1786, but was unsuccessful. A few years afterwards, availing himself of the political feelings of the period, he produced the tragedies of *Charles IX.*, *La Mort de Calas*, and the republican tragedies of *Gracchus* and *Timoleon*, which were received with great applause by the then dominant party, and procured him a seat in the National Convention. His last dramatic production, founded on the accession of Cyrus to the throne of the Medes, failed more completely even than his original piece, and led him to confine himself to translations and imitations from the Greek and German. His lyric productions, published in 1797, consist chiefly of odes imitated from Ossian. His other poems are devoted to the celebration of political events.

He was chosen deputy to the national convention, and afterwards president; was twice elected a member of the council of Five Hundred; and in 1799 was appointed a member of the tribunate. Under the régime of the first consul he had more ample leisure for literary pursuits, and at his suggestion to the Institute, wrote a historical and critical account of the most celebrated productions in French literature from 1788 to 1808, which was afterwards published under the title *Tableau Historique de l'Etat et des Progrès de la Littérature Française depuis* 1789. Chenier spent the rest of his life in retirement at Paris, where he died in 1811.

CHEOPS, or, as his name is written by Diodorus, Chemmis or Chembes, one of the first of the Egyptian kings, who is said to have built the pyramid called by his name, the largest and most ancient of those in the district of El Ghizeh. He died after a long and bloody reign of fifty years, and was succeeded by his brother Chephren or Cephren, who built the second of the pyramids, and for fifty-six years rendered himself as odious to his subjects as Cheops had been. See Pyramid.

CHEPSTOW, a market-town and river-port of England, county of Monmouth, on the Wye, 2 miles from its junction with the Severn, and 135 miles from London. Pop. (1851) 4295. It occupies the slope of a hill on the western bank of the river, and is environed by scenery of much beauty and grandeur. The town is generally well built, and the streets are broad and clean. The church, originally the conventual chapel of a Benedictine priory, has been recently restored to its former dimensions by the rebuilding of the chancel and transepts. The western entrance and other parts are richly decorated, and the interior contains many interesting monuments. The castle, founded in the eleventh century by W. Fitz-Osborn Earl of Hereford, and almost wholly rebuilt in the thirteenth, is still a magnificent pile. It stands on the summit of a cliff, the base of which is washed by the Wye and occupies about three acres of ground. The river is crossed by a fine iron bridge of five arches, erected in 1816. It is 532 feet in length, 20 feet wide, and the middle arch has a span of 112 feet. The river is navigable for large vessels as far as the bridge; but barges of from 18 to 30 tons can ascend as far as Hereford. From the narrowness and depth of the channel the tide rises suddenly and to a great height, frequently above 50, and it is said even to 70 feet, forming a dangerous bore. There are no manufactures, but the export trade is considerable. During 1852, 401 vessels of 10,712 tons entered, and 113 vessels of 7491 tons cleared at the port; and in the end of that year 58 vessels of 2533 tons were registered as belonging to the port. The exports are bark, iron, coal, cider, and millstones, large quantities of timber to the royal dockyards, and of grain to Bristol.

CHER, a central department of France, embracing the eastern part of the ancient province of Berry and part of Bourbonnais; bounded N. by the department of Loiret, W. by Loire-et-Cher and Indre, S. by Allier, and E. by Nièvre and the Loire. It is situated between N. Lat. 46. 18. and 47. 41., and between E. Long. 1. 50. and 3. 6. Area 2840 square miles. The surface of the department in general is extremely level, the only elevated districts being on the northern and north-western frontiers, which are skirted by a range of low hills. The principal rivers which traverse it, besides the Cher and its tributaries, are the Grand Sauldre and Petit Sauldre on the N.; but the Loire and Allier, though not falling within the department, drain the eastern districts, and are available for navigation. The Cher itself becomes navigable when it receives the Arnon and Yevre, and the communications of the province are greatly facilitated by the canal Du Berry, which traverses it in all its length, and the lateral canal of the Loire which stretches from Digoin to Briare. With the exception of the *Sologne*, a sandy and sterile tract in the N.W., the soil is generally fertile, but varies considerably in different localities. The most productive region is that on the E., which belongs to the valley of the Loire; the central districts are tolerably fertile but marshy, being often flooded by the Cher; while in the S. and S.W. there is a considerable extent of dry and fertile land. The department contains a comparatively large extent of pasturage, which has given rise to a considerable trade in horses, cattle, sheep, and wool for the northern markets. Among the agricultural productions hemp holds the first place; but wine, fruits, chestnuts, truffles, &c., are important articles of traffic. Mines of iron and coal are wrought; and marble, millstones, lithographic stones, manganese, gypsum, and porcelain clay are procured in different parts. The smelting of iron-ore and the manufacture of steel and cutlery is carried on to a considerable extent. The other manufactures are of coarse cloth and canvas, cotton and woollen gauze, porcelain, and toys. Cher is comprised in the fifteenth military division, and its tribunals hold of the imperial court of Bourges. It is divided into three arrondissements, cognominal with their capitals, of which the population and subdivision are as follows:—

Arrondissement.	Cantons.	Communes.	Pop. 1851.
Bourges	10	111	120,149
Sancerre	8	75	77,585
St Amand	11	121	108,530
	29	307	306,261

CHERASCO, a town of Piedmont, province of Mondovia, near the junction of the Stura and the Tanaro, 30 miles S.E. of Turin. It is well built, surrounded by walls, and watered by a canal from the Stura. Its principal manufacture is silk, and it has some trade in corn and wine. In 1796 its citadel and other fortifications were dismantled. Pop. 9000.

CHERBOURG, a naval station, fortified town, and seaport of France, department of La Manche, on the northern shore of the peninsula of Cotentin, at the mouth of the small river Divette. It stands on a bay formed by Cape Levi on the E. and Cape La Hogue on the W., and is distant 75 miles from the Isle of Wight, 41 miles W. by N. from St Lo, and 212 in the same direction from Paris. N. Lat. 49. 38., W. Long. 1. 38. The town is small and unimportant in itself. The houses are built of stone and roofed with slate; but the streets are narrow and dirty, and the only public buildings of any interest or importance are the

tower (a remnant of the old fortifications), the church close beside it, the Chapelle de Nôtre Dame du Vœu, the Hôtel de Ville, and the theatre. Cherbourg derives its chief importance from its naval and commercial harbours, which are distant from each other about half a mile. The former is cut out of the rock, and is capable of accommodating fifty men-of-war of the largest size. The depth of water at full tide is 50 feet, at low tide 25 feet. Connected with the harbour are the dry docks, the yards where the largest ships in the French navy are constructed, the magazines, rope walks, and the various workshops requisite for a naval arsenal of the first class. The works are carefully guarded on every side by redoubts and fortifications, and are commanded by the batteries on the overhanging hills so completely that the harbour of Cherbourg may fairly be pronounced impregnable. The commercial harbour at the mouth of the Divette communicates with the sea by a canal 650 feet in length and 54 in width. It consists of two parts, an outer harbour 262 yards long by 218 wide, and a basin 446 yards long and 138 wide, in which the depth of water is 19 feet at low tide. Outside these harbours is the triangular bay which forms the roads of Cherbourg. This bay is admirably sheltered by the land on every side but the north. To protect the shipping from the violence of the north winds the great *digue* or breakwater has been constructed. This immense work is 2½ miles in length; its breadth at its base 262 feet, and at its summit 101 feet. Its foundation was formed by massy wooden frames, which were sunk and filled with stones; and it is now protected from the waves by a parallel line of large blocks weighing each 44 tons. (For a detailed account of the breakwater of Cherbourg, see article BREAKWATER.) The trade of Cherbourg is considerable, and consists principally of cotton yarn, refined sugar, leather, and chemical products. A lace factory in the town gives employment to nearly 400 women. The principal articles of export, besides those already mentioned, are farm and dairy produce. The imports consist principally of colonial produce, and of coal, iron, and other articles required for the arsenal. Cherbourg possesses tribunals of first instance, of commerce, and of naval affairs, a departmental college, an academical society, public and naval libraries, and several museums. Pop. 24,212.

CHERIBON, or SHERIBON, a seaport-town on the N. coast of Java, capital of a district of the same name, and the residence of a Dutch governor, is situated at the head of a wide bay 125 miles E.S.E. of Batavia. Lat. 6. 48. S., Long. 108. 37. E. It was formerly a place of considerable importance, but in the early part of the present century a pestilential disorder carried off the greater part of its inhabitants. Though it has never fully recovered from the effects of this disaster, it has still a considerable trade. The town and harbour are defended by a fort. The district is very fertile, and produces the finest coffee raised in the island. Timber, cotton, indigo, sugar, and pepper, are exported in large quantities.

CHERRY. See HORTICULTURE and PLANTING.

CHERSO, an island of Illyria, government of Trieste, in the gulf of Quarnero, connected with the island of Osero by a bridge. It is about 35 miles in length, with an area of 105 square miles, and about 14,000 inhabitants. It is traversed by a range of mountains, forming natural terraces, on which vines and olive trees flourish. The other parts of the island are covered with bushes of laurel and mastic, but scarcely any large trees. There is a scarcity of springs, and the houses are generally furnished with cisterns for rain water. The capital of the same name, on the western side of the island, has a cathedral, several churches and monasteries, and 3500 inhabitants.

CHERSON. See KHERSON.

CHERSONESUS, or CHERRONESUS (from χέρσος or χέρρος, *land*, and νῆσος, *island*), in ancient geography signified *peninsula*. Thence Chersonesus Thracica, Chersonesus Taurica or Scythica, Chersonesus Cimbrica, respectively applied to the peninsula of the Dardanelles, the Crimea, and Jutland.

CHERTSEY (in Anglo-Saxon, *Ceortes Eye* or *Ceort's Island*), a market-town on the S. bank of the Thames, in the hundred of Godley, Surrey, 20 miles W.S.W. from London. It is connected with Middlesex by a bridge of seven arches, erected in 1785. The parish church, rebuilt in 1808, contains a monument to Charles James Fox, who resided at St Anne's Hill in the vicinity. It has also several dissenting chapels and schools, the principal of which is erected on a foundation yielding L.400 per annum, and gives education to 130 children of both sexes, of whom 60 belong to Chertsey. It is the seat of a county court, and contains both a literary and an agricultural institute. Its principal trade is in farm produce for the London markets; but bricks are also made there to a considerable extent. It communicates directly with London by a branch of the South-Western railway. During the heptarchy Chertsey was the residence of the South Saxon kings. Near it was a famous Benedictine abbey, rebuilt by Edgar in 963, but destroyed at the Reformation. No remains of the abbey are now visible. Pop. (1851) 2743.

CHERUB (plural, CHERUBIM), an angelic spirit, which in the celestial hierarchy is placed next to the seraphim. The term *cherub*, in Hebrew, is sometimes taken for a calf or ox. Ezekiel represents the face of the cherub as synonymous with the face of an ox. The word *cherub* in Syriac and Chaldee signifies to *till* or *plough*, which is the proper work of oxen. Cherub also signifies *strong* and *powerful*. Grotius says that the figures of the cherubim resembled that of a calf; Bochart likewise thinks that the cherubim had more likeness to the figure of an ox than to anything besides; Spencer is of the same opinion; and St John, in the Revelation, calls cherubim *beasts*. Josephus says that the cherubim were extraordinary creatures, of a figure unknown to mankind. Clemens Alexandrinus believes that the Egyptians imitated the cherubim of the Hebrews in the representations of their sphinxes and other hieroglyphical animals. Indeed all the descriptions which the Scripture gives us of cherubim differ from one another, but agree in representing them by a figure composed of various creatures, as a man, an ox, an eagle, and a lion. Such were the cherubim described by Ezekiel. The seraphim described by Isaiah had the figure of a man with six wings, two of which covered their faces, and two more covered their feet, while with the two others they flew. The cherubim which Solomon placed in the temple at Jerusalem are supposed to have been nearly of the same form. But those which St John describes in the Revelation were all eyes before and behind, and had each six wings. The first was in the form of a lion, the second in that of a calf, the third in that of a man, and the fourth in that of an eagle. The figure of the cherubim was not always uniform, since they are variously described as having the shapes of men, eagles, oxen, lions, and sometimes of all these put together. Moses likewise calls the symbolical or hieroglyphical representations which were embroidered on the veils of the tabernacle cherubim of costly work. Such were the symbolical figures which the Egyptians placed at the gates of their temples, and the images of the generality of their gods, which were commonly statues composed of the figures of men and animals combined on metaphorical or rather on allegorical principles.

CHERUBINI, MARIA LUIGI CARLO ZENOBI SALVADOR, was born at Florence 8th Sept. 1760, and died at Paris 15th March 1842. On the 19th of that month the funeral service was performed for him at the church of St Roche, and the requiem which he had composed for himself was sung. He received his earlier musical education at Florence, under the Felici, and Bizarri and Castrucci. In

1778 he was placed under Sarti at Bologna, with whom he studied four years, and to whose excellent method he owed his profound knowledge of counterpoint and fugue, and his taste and skill in the ideal style of composition. In 1784 he visited London, and brought out there two operas; and again in 1787, when he wrote some pieces for an opera by Cimarosa, and for one by Paesiello, which were produced at the King's Theatre. In 1788 he returned to Paris, where his new and superior style of music was at first not understood by the French; but in 1791 his *Lodoiska* at once wrought a revolution in the French school of composition, and the original genius of Cherubini was acknowledged and appreciated. His *Elisa* and his *Médée* added to his fame. Notwithstanding his superior talents and high European reputation, his position as an inspector of the conservatory at Paris was unworthy of him. Napoleon neglected him shamefully, and from a very mean motive—personal pique. At a private party, when Bonaparte was only general of the French army, he and Cherubini happened to make two of the company. The conversation turning upon music, Bonaparte contradicted Cherubini rudely, and attempted to dogmatise on the subject. Cherubini coolly said to him, "Citizen Bonaparte, in the art of war your knowledge is pre-eminent; but you should leave music to those who understand it." Napoleon never forgot or forgave this well-merited reproof; and, when master of France, could never be induced by those about him to do justice to Cherubini. In 1805 Cherubini went to Vienna, where he produced his *Faniska* with the greatest applause. Soon afterwards he composed a mass in F. for three voices, in a style quite new and admirable. After the restoration of the Bourbons he composed a number of masses and motets for the Royal Chapel, all of such excellence that even Beethoven, so chary of praise, declared Cherubini to be the greatest living composer of sacred music. Besides a great many operas and church compositions, &c., Cherubini produced some admirable instrumental music. His quartets for violins, viola, and violoncello have lately been heard and admired in London. His last work, published in 1835, was his *Cours de Contrepoint et de Fugue*, a summary of the lessons on strict composition which he had given for several years at the Paris conservatory of music. The writer of this article was personally acquainted with Cherubini at Paris in 1819, and through him received free access to the valuable library of the conservatory. (G. F. G.)

CHERUSCI, a celebrated tribe of ancient Germany, whose country was bounded on the E. by the Albis or Elbe, and on the W. by the Visurgis or Weser. Their history up to the time of Cæsar is comparatively obscure, but they seem to have been on the whole inclined to cultivate the friendship of the Roman people. In the time of Augustus, however, the cruelty and misgovernment of Varus, the Roman commander in these regions, drove the Cherusci into open rebellion. Under their leader Arminius they annihilated the army sent against them. This disaster preyed for years upon the mind of Augustus, who often started up at night out of his sleep exclaiming, "Quinctilius Varus, restore me my legions." All subsequent attempts of the Romans to reduce them again to subjection completely failed. In the course of their repeated wars with their neighbours, however, the Cherusci gradually lost the power and influence they once enjoyed. In the fourth century the Cherusci once more appear in history as members of the Frankish confederation.

CHESAPEAKE BAY, the largest bay in the United States of North America. Its entrance is in the state of Virginia, between Capes Charles and Henry, about 12 miles apart, and it extends inland 270 miles, dividing Maryland into two unequal parts. It is from 7 to 20 miles broad, and generally 9 fathoms deep. This great bay furnishes many fine harbours and a safe and convenient navigation. The Susquehanna, at its northern termination, and the Potomac and James on its west side, are the largest rivers that flow into it. The fisheries of the bay are of immense value to the inhabitants of its shores.

CHESELDEN, WILLIAM, an eminent surgeon and anatomist, was born at Barrow-on-the-Hill, Leicestershire, in 1688. He studied surgery under Mr Ferne of St Thomas's Hospital, whom he afterwards succeeded as head surgeon of that institution. Having devoted a large share of attention to the subject of lithotomy, he published a work on the high *Operation for the Stone;* and his skill as an operator in this department soon placed him at the head of his profession. He added greatly to his reputation by a successful couching operation performed on a youth of fourteen who had been blind from infancy. The details of the operation are given in the *Philosophical Transactions of the Royal Society* for 1828, and are valuable in a metaphysical point of view, as throwing considerable light on the doctrine of perception. Cheselden published also a *Text-Book of Anatomy*, a work on *Osteography* or *Anatomy of the Bones*, and a series of twenty-one plates, with descriptive letter-press appended to Gataker's Translation of Le Dran's *Operations of Surgery*. In 1737, disheartened by the frequent attacks to which his success exposed him, he retired from practice, and accepted the office of honorary surgeon to Chelsea Hospital. He died suddenly at Bath, of an attack of apoplexy, April 11, 1752.

CHESHAM, a market-town in the valley of the Chess, a tributary of the Colne, hundred of Burnham, Buckinghamshire, 26 miles N.W. from London. It contains an ancient cruciform parish church, and two dissenting places of worship, several schools, and an alms-house erected on an ancient foundation. It is the seat of a county court, and has a considerable manufacture of boots and shoes, straw-plait, and wooden ware, for the London markets. There are several paper-mills and a small silk-mill in the vicinity. Pop. (1851) 2496.

CHESHIRE, a maritime county in the N.W. of England, is bounded on the N. by Lancashire, on the N.E. by Yorkshire, on the E. by Derby and Stafford shires, on the S. by Shropshire and Denbighshire, on the W. by Flintshire, and on the N.W. by the Irish sea. Its greatest length from E. to W. is about 48 miles, and its greatest breadth from S. to N. about 33 miles. It possesses an area of 1105 square miles, or 707,075 acres, and is thus the eighteenth largest county in England.

The principal geological formation is the new red sandstone, which extends over the whole of the central and western parts of the county. The coal measures occur in the north-eastern district, which is within the boundary of what is usually called the great Lancashire coal-field. This county, in addition to coal, yields small quantities of both copper and lead; but its principal mineral product is salt, of which enormous quantities are raised from the mines, which are principally situated near Northwich. These mines when lighted up (as they are sometimes on special occasions) present a most singular and beautiful spectacle, almost realizing the ideal of a fairy palace, sparkling with crystal and gems. Besides the rock-salt from the mines, large quantities are manufactured from the brine springs in the neighbourhood. It is said that nearly 500,000 tons of rock and manufactured salt are exported annually.

The general aspect of the county is flat; but there are some hills on the east, on the Derbyshire and Yorkshire boundary; while for a few miles to the N.W. of Macclesfield, and also on the southern boundary of the county, the surface is somewhat broken and undulating. There is also a low range of hills near Chester. The greater part of the county is richly wooded, and the surface is diversified by numerous pools of water and small lakes, called meres. There are some extensive tracts of peat, and much of the

Cheshire.

county is very wet, having the surface covered with rushes and other subaquatic plants.

Cheshire possesses a number of streams and rivers, some of which are of considerable importance. The principal rivers are:—the Dee, which, rising in the Welsh mountains, forms the county boundary, separating it from Denbigh and Flint on the S.W., and, after traversing a portion of the county, forms a wide navigable estuary near Chester, and falls into the Irish sea; the Mersey, which rises in the Yorkshire hills, forms the county boundary along the whole of its northern edge, and after flowing in a nearly due W. course, and forming the important ports of Liverpool and Birkenhead, also falls into the Irish sea; the Weaver, which, after having received the Dane which rises in Derbyshire, flows in a N.W. course, and empties itself into the Mersey. By means of locks, this latter stream has been rendered navigable for vessels of 100 tons burthen as far as Northwich, which is ten miles from its mouth, and thus furnishes a ready means of transport for the produce of the salt mines.

The principal lakes are Combermere and Delamere, both of which have given titles to noble familes. The royal forest of Delamere is also within this county.

The climate is temperate, and somewhat moist, and the soil is for the most part fertile; but owing to the general flatness of the surface, much of the land is very wet and greatly in want of draining. Dairy farming is the description of agriculture principally pursued; the greater portion of the land is therefore in pasture. On some estates a good deal has been done in draining, and in afterwards applying bone-manure to the surface with the best effect; but, generally speaking, agriculture is in a very low condition, and the general management of the land discreditable alike to landlords and tenants. The principal agricultural produce is cheese, of which an immense quantity is annually produced; and it is somewhat singular that the best quality is generally obtained from the poorest lands. It is said that not less than 14,000 tons of Cheshire cheese are annually sold in the London market alone. Seldom more than one-fourth of a dairy farm is cultivated, the other three-fourths being in permanent pasture. The crops usually raised on the cultivated lands are beans, potatoes, wheat, turnips, and oats. The farms are seldom large, and the farmers are a hard-working, hard-living race of men. It is calculated that not more than one-seventeenth part of the whole county is waste land; but of the remainder a large portion is in natural pasture.

This county is everywhere intersected by railways and canals or navigable streams, and thus possesses means of communication second to no county in England. The celebrated Bridgewater canals which traverse it rank among the finest and most useful works of the kind in any country, and have been the means of developing the resources and industry of the county to a surprising extent.

The principal towns are Chester, Birkenhead, Macclesfield, Stockport, and Congleton. At Stockport the manufacture of cotton and hats is carried on on a large scale, while Macclesfield and Congleton are chief seats of the silk manufacture. A large trade is also carried on in bricks and draining pipes, for making which the clay soils of the county are well suited.

Cheshire returned but two members to parliament from 1543 to the period of the Reform act. Since that time it has returned ten, viz., two for the southern, and two for the northern division of the county; and two each for the city of Chester and boroughs of Macclesfield and Stockport. The constituency of the northern division in 1852 was 7494. The political influence is chiefly in the hands of Lord Stanley of Alderley, the Egertons of Oulton Park, the Earl of Stamford and Warrington, and the Leighs of High Leigh. The constituency of the southern division in 1852 was 8117. The political influence is chiefly in the hands of the Marquis of Westminster, the Marquis of Cholmondeley, and the Egertons of Oulton. The average gross rental of the county is estimated at 28s. 7d. per acre. The annual value of real property paying income-tax is L.2,062,283; and the amount of property assessed for the relief of the poor is L.1,593,157.

Chesne.

The population of the county by the last census was 455,725, giving an average of 412 persons to a square mile, or 1·6 acres to each person. Of the total number 222,386 were males, and 233,339 females. The number of inhabited houses, including the represented city and boroughs, was 85,260; uninhabited, 4341; and building, 845;—giving an average of 77 inhabited houses to a square mile, and 5·3 persons to each house. The following table gives the census returns for the last 50 years:—

YEARS.						Increase of population per cent. in fifty years.
1801.	1811.	1821.	1831.	1841.	1851.	
192,305	227,031	270,098	334,391	395,660	455,725	137

It is calculated that more than twenty-three per cent. of the population live by trade, manufactures, &c., nearly seven per cent. by agriculture; about one-eight of the whole population are in the condition of servants, labourers, &c.; upwards of three thousand follow professions; while eight thousand persons possess independent means.

Cheshire in 1844 occupied the nineteenth place in a table showing the ignorance of the kingdom, as illustrated by the numbers of men who signed the marriage registers with a mark—not being able to write. Its proportion above the average of ignorance was thus 0·4. In 1842–7 it occupied the thirty-fifth lowest position, in a table showing the crime of the kingdom, as illustrated by the criminal commitments of Wales to assizes and quarter sessions; its proportion above the average being 24·3. In a similar table showing the commitments for more serious offences against the person, and malicious offences against property, it occupied the forty-third or second worst place (Wales being taken in two divisions, and Yorkshire in three); the proportion above the average being 71·2. In a similar table showing the amount of bastardy in 1842, it occupied the fifth worst position; its proportion above the average being 40·3. In a similar table of pauperism for 1844, it occupied the fourth best place, its proportion under the average being 30·0.

CHESNE, André du, surnamed the Father of French history, was born at Ile-Bouchard in Touraine in the year 1584. He began his studies at Loudun, and finished them at Paris under the celebrated Julius Cæsar Boulanger. His favourite pursuits were geography and history, in which he made such rapid progress that at the age of eighteen he dedicated to his teacher his first book, entitled *Egregiarum seu electarum lectionum et antiquitatum liber*. He next translated into French the Satires of Juvenal with notes and illustrations. By these and other works he gained for himself the favour and protection of some of the leading men of his country. Cardinal Richelieu in particular, who was born in the same neighbourhood as Du Chesne, testified his esteem for him in a variety of ways. In 1608 Du Chesne married. The only fruit of his marriage was a son, who cultivated history with as much zeal, though not with the same success, as his father. In 1640 he was run over by a carriage and killed, while on his way from Paris to his country seat at Verrière.

His principal works are—*Les antiquites et recherches des villes, chateaux, &c., de toute la France; Histoire d'Angleterre, d'Ecosse, et d'Irlande; Histoire des Rois, Ducs, et Comtes de Bourgogne*, 1634, 2 vols. fol.; *Historiæ Normanorum Scriptores Antiqui*, 1619, fol.; *Historiæ Francorum Scriptores*, 5 vols. fol., 1636–49. Besides these Du Chesne published a great number of genealogical histories of illustrious French families; of which the best is said to be that of the house of Montmorency. His Lives of the French Cardinals and of the Saints of France have been published by the Bollandists, Mabillon, and others.

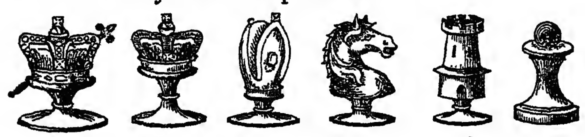
CHESS,

Chess.

A VERY ancient and ingenious game, performed by two persons, with thirty-two pieces of wood or ivory called men, on a square board divided into sixty-four equal squares, usually stained black and white alternately. Each player has sixteen men, those of the one player being usually either black or red, and those of the other white, in order to distinguish them.

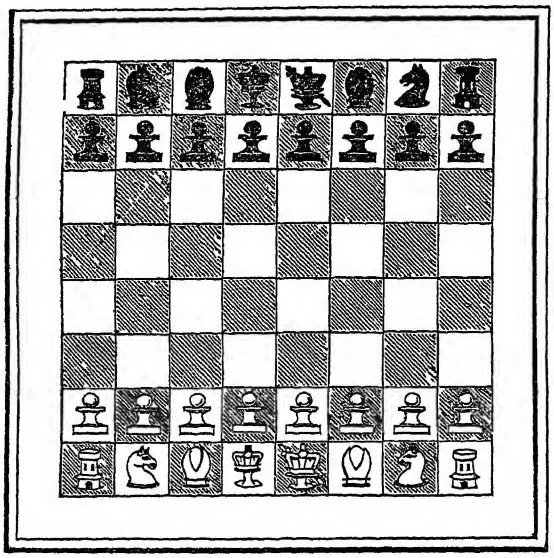
Of the sixteen men on either side, eight are called *Pieces*, and eight *Pawns*. The eight pieces consist of a *King*, a *Queen*, two *Castles* or *Rooks*, two *Bishops*, and two *Knights*.

The men may be thus represented:



King. Queen. Bishop. Knight. Rook. Pawn.

The following diagram represents the board, with the men as placed on it when a game is to be played:



Each row of squares running from the bottom to the top of the board is called a *file*. Each row of squares running from side to side is called a *rank* or *line*. Four lines of squares belong to the black men, and four to the white. A row of squares running obliquely from one side of the board to the other is called a *diagonal*. A diagonal consists either wholly of black squares or wholly of white.

The board must be so placed between the two players, that each of them may have a white corner at his right hand. This manner of placing the board, though not essential to the game, is invariably observed.

The eight pieces are ranked up on the first line of the board next each player, according to the following distribution: The two rooks occupy the two lateral squares which form the angles of the board; the two knights occupy the squares next to the rooks; the two bishops are next to the knights; and the king and queen occupy each of them one of the two centre squares of the line, *the queen being upon a square of her own colour*.[1] It follows, that when the pieces are properly placed, the white king will be found occupying the square to the right, and the black king the square to the left, each of his respective queen.

Chess.

The pieces on the king's side of the line are called the king's bishop, the king's knight, and the king's rook. Those on the queen's side are called the queen's bishop, the queen's knight, and the queen's rook.

The eight pawns are ranked up on the second line of squares, and take their denomination from the several pieces before which they are respectively placed. Thus, the pawn in the square in front of the king is called the king's pawn, the one in front of the queen is called the queen's pawn, and so on with the rest, as king's bishop's pawn, queen's bishop's pawn, king's knight's pawn, queen's knight's pawn, king's rook's pawn, queen's rook's pawn.

In like manner the *squares* of the board take their denomination from the several pieces. The square occupied by the king at the beginning of the game is called the king's square, the one occupied by the queen the queen's square, and so on. The square immediately in front of the king's square is called the king's second square, the one in front of his second square is his third square, and the one in front of his third is his fourth square. The eight pieces of each of the two players have thus their respective squares, and second, third, and fourth squares, exhausting among them the whole sixty-four squares of the board. For the sake of clearness, however, it is sometimes convenient to carry the numeration into the adverse side of the board. Thus, the square in front of the king's fourth is sometimes called his *fifth* square, and so on to the eighth square, which of course is the adverse king's square.

The *pawn* moves straight forward on its own file, one square at a time, except at first setting off, when, in the option of the player, it may move two squares at once. For example, if it be proposed to move the king's pawn, which stands on its own square, being the king's second square, it may be moved either to the king's third or to his fourth square, but afterwards it can be moved forward only one square at a time.

The pawn, although it moves straight forward, attacks and captures its adversaries diagonally or obliquely. Thus suppose a white pawn to be on its king's fourth square, and a black pawn to be also on its king's fourth square, the one pawn cannot attack and take the other; on the contrary, the one stops the other in its progress onward. But suppose the black pawn to be on its queen's fourth square, then the white pawn can attack and take the black pawn. This is done by removing the black pawn from the board, and advancing the white pawn obliquely, and placing it on the square left vacant by the removal of the black pawn; that is to say, the white pawn is removed from its own king's fourth square, and placed on the adverse queen's fourth square. It still retains the name of the king's pawn. When this pawn has again occasion to move, it goes straight forward on its new file, unless it should avail itself of another opportunity of making a capture, when it again passes obliquely to a square in another file. When a pawn has arrived at the eighth or last square of the file, it loses its character of a pawn, and may be converted into any piece.

[1] Sequitur regina colorem.

except the king, that the player chooses. He is said to *queen* his pawn when he carries it up to the ultimate square.

The *knight* moves in a manner somewhat difficult to be described. It leaps obliquely over an adjoining square to one of the next squares, having a colour different from the colour of the square which it leaves. For example, let the king's knight be on its own square; it may be moved to the king's second square, to the king's bishop's third square, or to the king's rook's third square; or, supposing it to be standing on its king's fourth square, it may be moved to the king's knight's third square, or to the king's bishop's second square, or to the queen's second square, or to the queen's bishop's third square, or to the adverse queen's bishop's fourth square, or to the adverse queen's third square, or to the adverse king's bishop's third square. On turning to the diagram, the reader will be able easily to follow and understand this description of the knight's move. It is the only piece that is allowed to move *over* another.

The *bishop* moves diagonally forward or backward any number of squares at a time, provided the course be open, by being free of other men. A bishop must necessarily continue to move over squares of a colour the same with that on which it was originally placed. The one bishop always moves upon black diagonals, the other upon white.

The *rook* or *castle* moves straight forward, straight backward, or straight across, any number of squares at a time, provided the intermediate squares be unoccupied by other men; that is to say, a rook moves either upon *files* or upon *lines*.

The *queen* can move either like a rook or like a bishop.

The *king* can move one square only at a time, and that backwards, or forwards, or sidewise, or obliquely. He can also, once in the course of a game, make the singular move called *castling*. Castling usually takes place for the double purpose of removing the king into a more secure situation, and of bringing a castle more into play; and it may be done either on the king's side of the board or on the queen's. When it is done on the king's side, the king and his rook are simultaneously lifted from their respective squares, and placed, the king on his knight's square, the rook on the bishop's. When it is done on the queen's side, the king and the queen's rook are lifted from their squares, and placed, the king on the queen's bishop's square, the rook on the queen's.

The adverse kings cannot approach each other so as to be on conterminous squares. One square at least must intervene between them. The reason of this obviously is, that if one king were to come to a square adjoining that occupied by the other, he would be within the range of his attack.[1]

All the *pieces* (it is otherwise with the pawns) *take* in the direction in which they move. The manner of taking is to place the attacking piece on the square of the piece or pawn captured, the captured piece being removed from the board. A player, however, is not obliged to take a piece or pawn under attack and subject to capture. He may take it or not as he thinks fit.

The principal technical terms made use of in chess-playing will now be explained.

CASTLING.—This has been treated of already.

CHECK.—When an attack is made upon a king by any piece or pawn, he is said to be *checked*. This will be best understood from a practical illustration. Let your king be upon his own square, and let your adversary play his queen to his king's second square. If there be no piece or pawn on any of the squares which separate the king and queen, your king is directly exposed to the action of the queen, and is said to be *checked* by her. The check is to be got the better of by capturing the queen, if she happen to be within the range of any of your men, or by interposing some piece between your king and the attacking queen, or by moving the king to another square beyond the scope of her action.

CHECK BY DISCOVERY, or DISCOVERED CHECK.—This takes place when the removal of an interposed piece opens up a check from another piece. For example, let your king be on his own square, and the adverse queen on her king's second square, and let all the intermediate squares of the file be vacant, except the adverse king's third, upon which third square his queen's bishop happens to be placed. It is evident that the interposition of this bishop covers or protects your king from the action of his queen. But if your adversary should play away his bishop from his king's third square, your king would be instantly exposed to the action of the queen; and this is called *check by discovery*, or *discovered check*.

CHECK-MATE.—The object of the game is to give check-mate. When the king is so assaulted and beset that he cannot move out of check, nor take the piece or pawn that checks him, nor interpose any man for his protection, he is *check-mated;* and the party giving the check-mate wins the game.

STALE-MATE.—When the king is *not* in check, but yet is so circumstanced that he cannot move without going into check, and when, at the same time, all his men are either off the board, or in such a situation that none of them can move, he is said to be *stale-mated*. When stale-mate is given, the game is held to be drawn.

DRAWN GAME.—A game is said to be drawn, when neither party can give check-mate to the other. This happens, 1*st*, where perpetual check is given to the adverse king without the possibility of his averting it; 2*dly*, where the force left on the board is not sufficient to give check-mate; 3*dly*, where the force left being sufficient, the party possessing it is unacquainted with the method of giving check-mate in fifty moves, as required by the laws;[2] 4*thly*, where both parties stand on the defensive, neither of them being inclined to hazard an attack; and, 5*thly*, where one of the kings is stale-mated.

DOUBLED PAWN.—A pawn is said to be doubled, when, by having made a capture, it has passed from its own file to another file, already possessing a pawn on some other square.

PASSED PAWN.—A pawn is said to be passed, when there is no adverse pawn to oppose its march to queen, nor any adverse pawns on the two adjacent files; or, if there be hostile pawns on the adjacent files, when it has already passed them.

EN PASSANT.—In explaining the pawn's moves, it was stated, that at first setting off a pawn may be played two squares at once. This statement, however, is subject to qualification. Suppose your king's pawn to be upon its own square, and your adversary to have a pawn on your queen's fourth square, it is evident that you cannot play your king's pawn two squares without passing over a square exposed to the action of your adversary's pawn, the square so exposed being your king's third. Now, your adversary is entitled to arrest, as it were, your pawn in its passage over that square, and to capture it. *You* play your pawn from king's second to king's fourth; *he*

[1] In *Il Giuoco Incomparabile Degli Scacchi*, this reason is given:—" *Non bene conveniunt, nec in una sede morantur Majestas, et Amor.*

[2] See Art. xxii. of the Laws.

lifts it up, and moves his own pawn obliquely from your queen's fourth square to your king's third; and this operation is called taking your pawn *en passant.* He may take it, however, or let it alone, just as he likes.

En Prise.—When a piece or pawn is liable to be taken by another, it is said to be *en prise* of that other.

Minor Pieces.—Knights and bishops are called minor pieces, because they are of less value than the other pieces.

To Gain the Exchange or Difference.—When a player wins his adversary's rook, in exchange for his own knight or bishop, he is said *to gain the exchange.* In the Edinburgh Chess Club the expression used is, to *gain the difference.*

Gambit.—This is a peculiar opening of a game, where a player sacrifices a pawn or piece, in order to remove the adverse king's pawn from its fourth square, and thus be the better enabled to make an attack. Examples of it will be given hereafter, from which its nature will be much more easily understood than from any general description or definition.

Relative Value of the Pieces.

King.—As the king can never be taken, and as the very existence of the game depends upon him, he can, of course, have no relative value. But his power both of attack and defence being considerable, he should be brought forward to action as soon as the more powerful pieces, particularly the queen, are off the board.

Queen.—The queen is the most powerful of all the pieces, being worth two rooks and a pawn. Towards the end of a game, when the board has become more open for the action of the rooks, her relative value is lessened a little, and she is then worth two rooks only. Properly speaking, however, this arises not from any diminution of power upon her part, but from an increase of power on the part of the rooks.

Rook.—The rook is next in value to the queen, and is reckoned equal to a minor piece and two pawns, or to five pawns. A rook increases in power of action as the board gets clear of other pieces and pawns; and it is the only piece except the queen that can give check-mate with no other assistance than its own king.

Bishop.—The bishop is worth more than three pawns, and less than four. It is reckoned of equal value with a knight. At the beginning of a game the king's bishop is more serviceable for attack than the queen's. Two bishops, with the assistance of the king, can give check-mate.

Knight.—The knight, like the bishop, is worth more than three pawns, but less than four. It is distinguished by these two peculiarities: *1st,* It is never *en prise* of the piece that it attacks, except when it attacks another knight; and, *2dly,* the piece attacked cannot get the better of the attack by the interposition of a third piece, but must itself move to another square. Two knights, with the assistance of the king, *cannot* give check-mate. A knight and bishop *can.*

It is usual with writers on chess to give a great many *general* instructions as to the mode of opening and conducting a game; but as such general instructions are of little or no practical use, we shall withhold them entirely, in order to make room for a few examples of the game, by going over which with the aid of a board and men, the reader will become much better acquainted with chess-playing, than if he were to peruse whole volumes of general observations.

The following are the laws usually observed in this country in playing the game:

1. The chess-board must be placed in such a manner that each player may have a white square corner on his right hand. If the board be improperly placed, and the mistake not discovered till after four moves have been played on each side, it must remain as it is till the end of the game.

2. If the pieces or pawns be improperly placed, the player who first perceives it may insist on the mistake's being rectified, provided four moves on each side have not been played.

3. If a player begin a game without having all his pieces, and if he do not perceive it until the fourth move has been played, he must finish the game without the pieces or pawns which he has forgotten.

4. When the game is played *even,* the players must draw lots for the first move; after the *first* game the move belongs alternately to each player.[1]

5. The player who gives odds has always the advantage of the move; except, of course, in those games where the move is also given to the inferior player; such, for example, as the *pawn and move,* &c.

6. When a player has *touched* a piece he must *move* it. *N. B.*—If a piece be not placed exactly in the centre of its square, or if it should fall, the player must say *J'adoube* in placing it properly, else his adversary may compel him to play it.

7. As long as a player holds a piece, he is at liberty to play it where he chooses; but when he has *let it go,* he cannot recal his move.

8. If a player *touch* one of his adversary's pieces without saying *J'adoube,* he may be compelled to take it; if the piece cannot be taken, the player must move his king; and if neither the piece nor the king can be moved, no penalty shall be inflicted.

9. If a player should, by mistake, play one of his adversary's pieces instead of his own, his adversary may compel him either to take it, if it can be taken, to replace it where it was, or to let it remain where he played it.

10. If a player take one of his adversary's pieces with a piece that cannot take it without a false move, his adversary may compel him either to take it with any other piece, or to play the piece which he has touched.

11. If a player take one of his pieces with another of his own, his adversary may oblige him to play either of the two pieces.

12. If a player make a false move, his adversary may oblige him to let the piece remain where he played it; or to play it to some other square; or to replace the piece where it previously was, and to play the king instead of it.

13. If a player should play two successive moves, it is in his adversary's power to oblige him to put back the *second* move; or, if he choose it, he may insist on continuing the game, as if only *one* move had been played.

14. A pawn that is pushed two squares may be taken *en passant,* by the adversary's pawn.[2]

15. The king cannot castle: *1st,* If he has moved; *2dly,* if he be in check; *3dly,* if any of the squares over which he moves in castling be occupied by or under the power of one of his adversary's pieces; and, *4thly,* if the rook has moved. A player who castles in either of these *four*

[1] In Germany he who wins the game has the advantage of playing first the next game.

[2] This is not the case in Italy; a pawn is allowed to pass *en prise,* which is called *passar battaglia.*

cases must put back the move; and his adversary has the option of compelling him to play either the king or the rook with which he intended to castle.

16. If a player touch one of his pieces which cannot be moved without placing his king in check, he must play his king; and if the king cannot move, no penalty is to be inflicted.

17. Whenever a player attacks his adversary's king, he must say *check;* and if he forget to say it, the adversary needs not move his king, or take notice of the check; and if the player who did not say *check*, should, on the next move, attack the queen, or any of his adversary's pieces, and say *check*, the player whose king is in check may put back his last move, and, instead of it, remove his king, or cover the check.

18. If the king have been in check during two or more moves, and it be not possible to ascertain how it happened, he whose king is in check may, as soon as he perceives it, put back his last move, and remove his king, or cover the check.

19. If a player say *check* without giving check, and his adversary should in consequence move his king, or touch any piece to cover the check, and should afterwards perceive that he is *not in check*, he may put back his last move, provided his opponent have not already played his next move.

20. If a player has moved previously to perceiving a false move, or any other mistake which his adversary may have committed, he can no longer insist on the penalty: he should have noticed the mistake before he *moved* or *even touched* a piece.

21. When a player has pushed a pawn *to queen*, he is at liberty to make a *second queen*, a *third rook*, or any other piece which he may deem more useful for his attack or defence.

22. At the end of a game, when a player remains with a rook and a bishop against a rook, with both bishops, or with a knight and bishop, against the king, &c. if he cannot check-mate his adversary in *fifty* moves, the game shall be considered as a drawn game.

But if a player engage to check-mate his adversary with a marked pawn, or with any particular piece, the number of moves is then unlimited.

23. If the king be *stale-mated*, the game is a *drawn game.*

Explanation of the Abbreviated Terms made use of in the Notation of the Games.

K.	signifies	King or King's.
Q.	...	Queen or Queen's
R.	...	Rook or Rook's.
B.	...	Bishop or Bishop's.
Kt.	...	Knight or Knight's.
P.	...	Pawn or Pawn's.
Sq.	...	Square.
Adv.	...	Adverse or Adversary's.
Chg.	...	Checking.

First Game,

Being the first of the match (1824–8) between the London and Edinburgh Chess Clubs. White represents the Edinburgh side, black the London.

White.	Black.
1. K. P. two squares.	1. K. P. two squares.
2. K. B. to Q. B. 4th sq.	2. K. B. to Q. B. 4th sq.
3. Q. B. P. one sq.	3. Q. to K. 2d sq.
4. K. Kt. to K. B. 3d sq.	4. Q. P. one sq.
5. Q. P. one sq.	5. K. Kt. to K. B. 3d sq.
6. Q. to K. 2d sq.	6 King castles.
7. Q. B. to adv. K. Kt. 4th sq.	7. K. R. P. one sq.
8. Q. B. to K. R. 4th sq.	8. Q. B. to K. 3d sq.
9. K. B. to Q. Kt. 3d sq.	9. B. takes B.
10. Q. R. P. takes B.	10. Q. Kt. to Q. B. 3d sq.
11. Q. Kt. to Q. 2d sq.	11. Q. to K. 3d sq.
12. P. to Q. Kt. 4th sq.	12. K. B. to Q. Kt. 3d sq.
13. Q. B. takes Kt.	13. Q. takes B.
14. Q. Kt. to Q. B. 4th sq.	14. Q. to K. 3d sq.
15. K. Kt. to K. R. 4th sq.	15. Q. Kt. to K. 2d sq.
16. K. Kt. P. two sqrs.	16. Kt. to K. Kt. 3d sq.
17. K. Kt. takes Kt.	17. K. B. P. takes Kt.
18. K. castles with K. R.	18. K. R. to adv. K. B. 4th sq.
19. K. R. P. one sq.	19. Q. R. to K. B. sq.
20. Kt. takes B.	20. Q. R. P. takes Kt.
21. K. B. P. one sq.	21. Q. to K. B. 3d sq.
22. K. to K. Kt. 2d sq.	22. Q. B. P. one sq.
23. K. R. to K. B. 2d sq.	23. P. to Q. Kt. 4th sq.
24. Q. to K. 3d sq.	24. K. R. P. one sq.
25. K. to K. Kt. 3d sq.	25. Q. to K. Kt. 4th sq.
26. Q. R. to K. sq.	26. K. to K. R. 2d sq.
27. Q. to K. 2d sq.	27. R. to K. R. sq.
28. Q. to K. 3d sq.	28. K. to K. Kt. sq.
29. R. to K. R. 2d sq.	29. K. R. P. takes P.
30. K. R. P. takes P.	30. R. takes K. B. P. chg.
31. K. takes R.	31. Q. takes Q. chg.
32. K. takes Q.	32. R. takes R.
33. R. to Q. R. sq.	33. R. to adv. K. R. 3d sq. chg.
34. K. to K. 2d sq.	34. R. to adv. K. R. 2d sq. chg.
35. K. to K. 3d sq.	35. K. to adv. K. R. 3d sq. chg.

The game was here declared to be drawn.

As this game happened to be drawn, we shall give a variation of it, in order to make it terminate with a check-mate. Supposing white to have played, for its 26th move, K. R. P. one square, instead of Q. R. to K. sq. the following would probably have been the train of moves:

26. K. R. P. one sq.	26. K. R. takes K. Kt. P. chg.
27. K. B. P. takes R.	27. Q. takes Q. chg.
28. K. to his Kt. 2d.	28. R. takes K. R. chg.
29. K. to his R. sq.	29. Q. to ad. K. R. 3d chg.
30. K. to his Kt. sq.	30. Q. to ad. K. Kt. 2d sq. or to ad. K. R. 2d sq. giving check-mate.

Second Game.—(From Greco.)

1. K. P. two squares.	1. K. P. two squares.
2. K. Kt. to K. B. 3d sq.	2. Q. P. one sq.
3. K. B. to Q. B. 4th sq.	3. Q. B. to adv. K. Kt. 4th sq.
4. K. R. P. one sq.	4. Q. B. to K. R. 4th sq.
5. Q. B. P. one sq.	5. K. Kt. to K. B. 3d sq.
6. Q. P. one sq.	6. K. B. to K. 2d sq.
7. Q. B. to K. 3d sq.	7. K. castles.
8. K. Kt. P. two squares.	8. Q. B. to K. Kt. 3d sq.
9. K. Kt. to K. R. 4th sq.	9. Q. B. P. one sq.
10. K. Kt. takes Q. B.	10. K. R. P. takes K. Kt.
11. K. R. P. one sq.	11. Q. Kt. P. two sqrs.
12. K. B. to Q. Kt. 3d sq.	12. Q. R. P. two sqrs.
13. Q. R. P. two sqrs.	13. Q. Kt. P. one sq.
14. K. R. P. one sq.	14. P. takes K. R. P.
15. K. Kt. P. one sq.	15. K. Kt. to adv. K. Kt 4th sq.
16. K. R. takes P.	16. K. Kt. takes Q. B
17. K. R. to adv. K. R. sq. chg.	17. K. takes K. R.

Chess.

White.	Black.
18. Q. to ad. K. R. 4th sq. chg.	18. K. to K. Kt. sq.
19. K. Kt. P. one sq.	19. K. R. to K. sq.
20. Q. to adv. K. R. 2d sq. chg.	20. K. to K. B. sq.

21. Q. to adv. K. R. sq. giving check-mate.

Third Game.

This is an example of the king's gambit. It is from Philidor, and is his seventh back-game on the first gambit.

1. K. P. two squares.	1. K. P. two squares.
2. K. B. P. two sqrs.	2. K. P. takes K. B. P.
3. K. Kt. to K. B. 3d sq.	3. K. Kt. P. two sqrs.
4. K. B. to Q. B. 4th sq.	4. K. B. to K. Kt. 2d sq.
5. K. R. P. two sqrs.	5. K. R. P. one sq.
6. Q. P. two sqrs.	6. Q. P. one sq.
7. Q. B. P. one sq.	7. Q. B. P. one sq.
8. Q. to K. 2d sq.	8. Q. B. to K. 3d.
9. K. B. takes Q. B.	9. K. B. P. takes B.
10. K. P. one sq.	10. Q. P. takes K. P.
11. Q. P. takes P.	11. Q. Kt. to Q. 2d sq.
12. K. Kt. P. one sq.	12. K. Kt. P. one sq.
13. K. Kt. P. takes P.	13. K. Kt. P. takes Kt.
14. Q. takes P.	14. Q. to K. 2d sq.
15. Q. Kt. to Q. 2d sq.	15. K. castles with Q. R.
16. Q. Kt. P. two sqrs.	16. K. R. P. one sq.
17. Q. Kt. to K. 4th sq.	17. Q. Kt. to Q. Kt. 3d sq.
18. B. to K. 3d sq.	18. K. Kt. to K. R. 3d sq.
19. B. to ad. Q. B. 4th sq.	19. Q. to Q. B. 2d sq.
20. Q. R. P. two sqrs.	20. K. B. to its own sq.
21. Q. R. P. one sq.	21. B. takes B.
22. P. takes B.	22. Q. Kt. to Q. 2d sq.
23. Kt. to ad. Q. 3d sq. chg.	23. K. to Q. Kt. sq.
24. Q. R. to Q. Kt. sq.	24. Q. Kt. takes P. at Q. B. 4th sq.
25. Kt. takes Q. Kt. P.	25. Q. Kt. takes Kt.
26. Q. R. P. one sq.	26. K. to Q. R. sq.
27. R. takes Kt.	27. Q. to Q. B. sq.
28. K. R. to K. R. 2d sq.	28. Q. R. to Q.'s 2d sq.
29. K. R. to Q. Kt. 2d sq.	29. K. R. to K. R. 2d sq.
30. Q. takes Q. B. P.	30. Q. takes Q.

31. Q. R. to ad. Q. Kt. sq. giving check-mate.

Fourth Game.

This is an example of Cunningham's gambit.

1. K. P. two sqrs.	1. K. P. two sqrs.
2. K. B. P. two sqrs.	2. K. P. takes K. B. P.
3. K. Kt. to K. B. 3d sq.	3. K. B. to K. 2d sq.
4. K. B. to Q. B. 4 sq.	4. K. B. to ad. K. R. 4 chg.
5. K. Kt. P. one sq.	5. P. takes P.
6. K. castles.	6. K. P. takes ad. K. R. P. chg.
7. K. to K. R. sq.	7. K. B. to K. 2d sq.
8. K. B. takes K. B. P. chg.	8. K. takes B.
9. Kt. to ad. K. 4th sq. chg. and discovering check from R.	9. K. to his 3d sq.
10. Q. to K. Kt. 4th sq. chg.	10. K. takes Kt.
11. Q. to ad. K. B. 4th sq. chg.	11. K. to his Q. 3d sq.

12. Q. to ad. Q. 4th sq. giving check-mate.

Fifth Game.

This is an example of Salvio's gambit.

1. K. P. two sqrs.	1. K. P. two sqrs.
2. K. B. P. two sqrs.	2. K. P. takes P.
3. K. Kt. to K. B. 3d sq.	3. K. Kt. P. two sqrs.
4. K. B. to Q. B. 4th sq.	4. K. Kt. P. one sq.
5. K. Kt. to adv. K. 4th sq.	5. Q. to ad. K. R. 4th sq. chg
6. K. to his B.'s sq.	6. K. Kt. to K. B. 3d sq.
7. K. B. takes K. B. P. chg.	7. K. to Q. sq.
8. Q. P. two sqrs.	8. K. Kt. takes K. P.
9. Q. to K. 2d sq.	9. K. Kt. to ad. K. Kt. 3d sq. chg.
10. K. R. P. takes K. Kt.	10. Q. takes K. R. chg.
11. K. to his B.'s 2d.	11. P. takes P. chg.
12. K. takes P.	12. Q. takes Q. B.
13. K. Kt. to ad. Q. B. 3d. sq. chg.	13. Kt. or P. takes K. Kt.

14. Q. to ad. K. sq. giving check-mate.

Sixth Game.

This is an example of the Muzio gambit. This mode of opening a game is at present very much practised among the leading chess-players in London.

1. K. P. two sqrs.	1. K. P. two sqrs.
2. K. B. P. two sqrs.	2. P. takes P.
3. K. Kt. to K. B. 3d sq.	3. K. Kt. P. two sqrs.
4. K. B. to Q. B. 4th sq.	4. K. Kt. P. one sq.
5. King castles.	5. P. takes Kt.
6. Q. takes P.	6. Q. to K. B. 3d sq.
7. K. P. one sq.	7. Q. takes K. P.
8. Q. P. one sq.	8. K. B. to K. R. 3d sq.
9. Q. B. to Q. 2d sq.	9. K. Kt. to K. 2d sq.
10. Q. Kt. to B. 3d sq.	10. Q. B. P. one sq.
11. Q. R. to K. sq.	11. Q. to Q. B. 4th sq. chg.
12. K. to his R.'s sq.	12. Q. P. two sqrs.
13. Q. to ad. K. R.'s 4 sq.	13. Q. to her 3d sq.
14. K. B. takes P.	14. P. takes B.
15. Kt. takes P.	15. Q. Kt. to B. 3d sq.
16. Q. B. to Q. Kt. 4th.	16. Q. to K. Kt. 3d, offering an exchange of Queens.
17. B. takes Kt.	17. If he should take Q. with Q., you give him check-mate by playing Kt. to ad. K. B. 3d sq.; taking B. with Kt. would be bad, therefore he plays B. to K. 3d sq.
18. Q. to K. B. 3d.	18. Kt. takes B.
19. Kt. to ad. Q. B. 2d. chg.	19. K. to Q. 2d sq.
20. Kt. takes B.	20. P. takes Kt.
21. Q. takes Q. Kt. P. chg.	21. K. to Q. 3.

22. You may draw the game by constantly checking, and keeping adv. K. to Q. 2d or Q. 3d sq., neither of which squares he can quit without losing his knight, by which he would have the worst of the game. If not satisfied with a drawn game, you may at your 22d move play Q. B. P. two squares, having an excellent game. It would take up too much space for us to continue the analysis.

Seventh Game.

This is an example of Damiano's gambit.

1. K. P. two sq.	1. K. P. two sq.
2. K. Kt. to K. B. 3d sq.	2. K. B. P. one sq.
3. K. Kt. takes K. P.	3. K. B. P. takes K. Kt.
4. Q. to ad. K. R. 4th sq. chg.	4. K. to his 2d sq.
5. Q. takes K. P. chg.	5. K. to K. B. 2d sq.
6. K. B. to Q. B. 4th sq. chg.	6. K. to K. Kt. 3d sq.
7. Q. to ad. K. B. 4th sq. chg.	7. K. to K. R. 3d sq.
8. Q. P. two sqrs. chg.	8. K. Kt. P. two sqrs.
9. K. R. P. two sqrs.	9. K. to K. Kt. 2d sq.
10. Q. to ad. K. B. 2d sq. chg.	10. K. to K. R. 3d sq.

11. K. R. P. takes P. giving check-mate.

Eighth Game.

We shall conclude our examples by giving the fifth and last game of the match between the London and Edinburgh Chess Clubs. It is one of the most singular and inte-

resting games on record. It is an example of what is called the "Queen's Pawn Two" Game. The white men represent Edinburgh, the black London.

White.	Black.
1. K. P. two sqrs.	1. K. P. two sqrs.
2. K. Kt. to K. B. 3d sq.	2. Q. Kt. to Q. B. 3d sq.
3. Q. P. two sqrs.	3. Q. Kt. takes P.
4. Kt. takes Kt.	4. P. takes Kt.
5. Q. takes P.	5. K. Kt. to K. 2d sq.
6. K. B. to Q. B. 4th sq.	6. Kt. to Q. B. 3d sq.
7. Q. to adv. Q. 4th sq.	7. Q. to K. B. 3d sq.
8. Kt. to Q. B. 3d sq.	8. K. B. to ad. Q. Kt. 4th sq.
9. Q. B. to Q. 2d sq.	9. Q. P. one sq.
10. K. B. to adv. Q. Kt. 4th sq.	10. Q. B. to Q. 2d sq.
11. Q. to Q. B. 4th sq.	11. K. B. to Q. B. 4th sq.
12. K. castles with K. R.	12. K. castles with K. R.
13. Q. to Q. 3d sq.	13. Kt. to K. 4th sq.
14. Q. to K. Kt. 3d sq.	14. B. takes B.
15. Kt. takes B.	15. Q. B. P. one sq.
16. Kt. to Q. B. 3d sq.	16. Kt. to adv. Q. B. 4 sq.
17. B. to adv. K. Kt. 4th sq.	17. Q. to K. Kt. 3d sq.
18. Q. Kt. P. one sq.	18. K. B. P. one sq.
19. B. to Q. B. sq.	19. Q. takes Q.
20. K. R. P. takes Q.	20. B. to adv. Q. 4th sq.
21. P. takes Kt.	21. B. takes Kt.
22. Q. R. to Q. Kt. sq.	22. Q. Kt. P. one sq.
23. K. R. to Q. sq.	23. Q. R. to K. sq.
24. Q. R. to Q. Kt. 3d sq.	24. B. to Q. R. 4th sq.
25. K. B. P. one sq.	25. K. B. P. one sq.
26. P. takes P.	26. Q. R. to adv. K. 2d sq.
27. P. to K. Kt. 4th sq.	27. R. takes Q. B. P.
28. B. to K. B. 4th sq.	28. R. takes P. at ad. Q. B. 4th sq.
29. B. takes Q. P.	29. K. R. to K. sq.
30. Q. R. to Q. R. 3d sq.	30. K. R. P one sq.
31. B. to adv. Q. B. 2d sq.	31. K. R. to K. 2d sq.
32. K. R. to adv. Q. sq. chg.	32. K. to K. R. 2d sq.

60. K. to adv. K. R. 2d sq.	

At this point the London Club resigned the game and lost the match.

It is stated in the report of the match by the Edinburgh committee, that the match, which was played by correspondence, was begun on the 23d of April 1824, and finished on the 31st of July 1828. The first and third games were drawn, the fourth was won by the London Club, and the second and fifth were won by the Edinburgh Club.

METHODS OF GIVING CHECK-MATE.

1. *With a Rook and King against a King.*

Situation of the Pieces.

King at adv. King's 4th sq. King's Rook at its own sq.	King at his second sq.
1. R. to ad. K. R. 2d sq. chg.	1. K. to his sq.
2. K. to ad. K. 3d sq.	2. K. to his Q. sq.
3. R. to ad. K. Kt. 2d sq.	3. K. to Q. B. sq.
4. K. to ad. Q. 3d sq.	4. K. to Q. Kt. sq.
5. K. to ad. Q. B. 3d sq.	5. K. to Q. R. sq.
6. K. to ad. Q. Kt. 3d sq.	6. K. to Q. Kt. sq.
7. R. to ad. K. Kt. sq. giving check-mate.	

2. *With two Bishops and a King against a King.*

Situation of the Pieces.

King at ad. Q. Kt. 4th sq. K. B. at ad. K. B. 4th sq. Q. B. at ad. King's 2d sq.	King at Q. Kt.'s sq.
1. Q. B. to ad. Q. 3d sq. chg.	1. K. to Q. Kt. 2d sq.
2. K. B. to ad. Q. 2d sq.	2. K. to Q. R. 2d sq.
3. K. B. to ad. Q. B. sq.	3. K. to Q. R. sq.
4. K. to ad. Q. B. 3d sq.	4. K. to Q. R. 2d sq.
5. K. to ad. Q. B. 2d sq.	5. K. to Q. R. sq.
6. K. B. to ad. K. Kt. 2d sq. chg.	6. K. to Q. R. 2d sq.
7. Q. B. to ad. Q. B. 4th sq. giving check-mate.	

3. *With a Bishop, Knight, and King, against a King.*

This is perhaps the most difficult check-mate, and, it may also be added, the most beautiful.

Situation of the Pieces.

King at ad. K. B. 3d sq. K. B. at ad. K. B. 4th sq. Kt. at ad. K. Kt. 4th sq.	King at K. R.'s sq.[1]
1. Kt. to ad. K. B. 2d sq. chg.	1. K. to K. Kt. sq.
2. B. to K. 4th sq.	2. K. to K. B. sq.
3. B. to ad. K. R. 2d sq.	3. K. to his own sq.
4. Kt. to ad. K. 4th sq.	

[1] The king cannot be check-mated at this corner of the board. He must be forced over to a corner square, subject to the action of the bishop.

White.	Black.
First Defence.	
	4. K. to K. B. sq.
5. Kt. to ad. Q. 2d sq. chg.	5. K. to his own sq.
6. K. to ad. K. 3d sq.	6. K. to Q.'s sq.
7. K. to ad. Q. 3d sq.	7. K. to his own sq.[1]
8. B. to ad. K. Kt. 3d sq. chg.	8. K. to Q.'s sq.
9. Kt. to ad. Q. B. 4th sq.	9. K. to Q. B. sq.
10. B. to ad. K. B. 2d sq.	10. K. to Q. sq.
11. Kt. to ad. Q. Kt. 2d sq. chg.	11. K. to Q. B. sq.
12. K. to ad. Q. B. 3d sq.	12. K. to Q. Kt. sq.

14. B. to ad. K. 3d sq. chg.	14. K. to Q. Kt. sq.
15. Kt. to ad. Q. B. 4th.	15. K. to Q. R.'s sq.
16. B. to ad. Q.'s 2d sq.	16. K. to Q. Kt. sq.
17. Kt. to ad. Q. R. 3d sq. chg.	17. K. to Q. R. sq.

18. B. to ad. Q. B. 3d sq. giving check-mate.

Second Defence.

	4. K. to Q. sq.
5. K. to ad. K. 3d sq.	5. K. to Q. B. 2d sq.
6. Kt. to ad. Q. 2d sq.	6. K. to Q. B. 3d sq.
7. B. to Q. 3d sq.	7. K. to Q. B. 2d sq.
8. B. to ad. Q. Kt. 4th sq.	8. K. to Q. sq.
9. Kt. to ad. K. 4th sq.	9. K. to Q. B. 2d sq.
10. Kt. to Q. B. 4th sq.	10. K. to Q. sq.
11. K. to ad. Q. 3d sq.	11. K. to Q. B. sq.
12. Kt. to ad. Q. R. 4th.	12. K. to Q. sq.
13. Kt. to ad. Q. Kt. 2d sq. chg.	13. K. to Q. B. sq.
14. K. to ad. Q. B. 3d sq.	14. K. to Q. Kt. sq.
15. Kt. to ad. Q. 3d sq.	15. K. to Q. R. 2d sq.
16. K. to ad. Q. B. 2d sq.	16. K. to Q. R. sq.
17. B. to Q. B. 4th sq.	17. K. to Q. R. 2d sq.
18. Kt. to ad. Q. B. sq. chg.	18. K. to Q. R. sq.

19. B. to ad. Q. 4th sq. giving check-mate.

4. *With a Queen and King against a Rook and King.*

Situation of the Pieces.

King at ad. K. B. 3d sq.	King at K. R. 2d sq.
Queen at ad. K. sq.	Rook at K. Kt. 2d sq.

1. Q. to K. 4th sq. chg.	1. K. to R. sq. or to Kt. sq.
2. Q. to ad. Q. R. sq. chg.	2. K. to K. R. 2d sq.
3. Q. to ad. K. sq.[2]	3. If he should play K. to K. R. 3d, you play Q. to ad. K. B. sq. and at your next move you gain his Rook.

If he should play his R. to your K. Kt. 4th, you play Q. to ad. K. R. 4th sq. checking, and then gain the Rook. Therefore he plays R. to ad. K. Kt. 3d.

4. Q. to K. 4th sq. chg.	4. K. to K. Kt. sq.
5. Q. to Q. B. 4th sq. chg.	5. K. to K. R. sq. or to K. R. 2d sq.
6. Q. to K. R. 4th sq. chg.	6. K. to K. Kt. sq.
7. Q. takes R. chg.	7. K. to K. B. sq.

8. Q. to ad. Q Kt. sq. giving check-mate.

If he had, at his third move, played R. to your K. Kt. 2d, you would have checked with your Q. at K. 4th sq. gaining the Rook.

Again, let his move be..........3. R. to ad. K. Kt. sq.

4. Q. to ad. Q. 2d sq. chg.	4. K. to K. R. sq.

White.	Black.
5. Q. to ad. Q. B. sq. chg.	5. K. to K. R. 2d sq.[3]
6. Q. to ad. Q. B. 2d sq. chg.	6. K. to K. Kt. sq.
7. Q. to ad. Q. Kt. sq. chg.	7. K. to K. R. 2d sq.
8. Q. to K. R. 2d sq. chg.	8. K. to K. Kt. sq.
9. Q. takes R. chg.	9. K. to K. B. sq.
10. Q. to ad. K. Kt. 2d sq. chg.	10. K. to his own sq.

11. Q. to ad. K. 2d sq. giving check-mate.

5. *With a Rook, Bishop, and King, against a Rook and King.*

Situation of the Pieces.

K. at ad. K. 3d sq.	K. at his sq.
R. at Q. B. sq.	R. at Q. 2d sq.
B. at ad. K. 4th sq.	

1. R. to ad. Q. B. sq. chg.	1. R. to Q. sq.
2. R. to ad. Q. B. 2d sq.	2. R. to ad. Q. 2d sq.
3. R. to ad. Q. Kt. 2d sq.	3. R. to ad. Q. sq.
4. R. to ad. K. Kt 2d sq.	

First Defence.

	4. K. to K. B. sq.
5. R. to ad. K. R. 2d sq.	5. R. to ad. K. Kt. sq.
6. R. to ad. Q. B. 2d sq.	6. If he were to play K. to Kt. sq. you would check with R. at ad. Q. B. sq., driving his K. to K. R. 2d; then check with R. at ad. K. R. sq.; then, when he moved his K. to K. Kt. 3d sq. you would check with Rook at ad. K. Kt. sq., gaining his Rook. To avoid this consequence he plays R. to K. Kt. 3d sq. chg.
7. B. to ad. K. B. 3d sq.	7. K. to Kt. sq.
8. R. to ad. Q. B. sq. chg.	8. K to K. R. 2d sq.

9. R. to ad. K. R. sq. giving check-mate.

Second Defence.

	4. R. to ad. K. B. sq.
5. B. to K. Kt. 3d sq.	5. If he were to play K. to K. B. sq., he would ultimately be check-mated, as shown below. At present he plays R. to ad. K. B. 3d sq.
6. B. to ad. Q. 3d sq.	6. R. to ad. K. 3d sq. chg.
7. B. to ad. K. 4th sq.	7. R. to ad. K. B. 3d sq.
8. R. to ad. K. 2d sq. chg.	8. K. to K. B. sq.
9. R. to ad. Q. 2d sq.	9. K. to K. Kt. sq.
10. R. to ad. K. Kt. 2d sq. chg.	10. K. to K. B. sq.
11. R. to K. Kt. 4th sq.	11. K. to his sq.
12. B. to K. B. 4th sq.	12. K. to K. B. sq.
13. B. to ad. Q. 3d sq., or to ad. K. R. 3d sq. chg.	13. K. to his sq.
14. R. to ad. K. Kt. sq. chg.	14. R. interposes.

15. R. takes R. giving check-mate.

Supposing him to have played differently at his fifth move of the second defence, he would still have been check-mated. Thus, 5. K. to K. B. sq.

6. R. to K. Kt. 4th sq.	6. K. to his own sq.
7. R. to Q. B. 4th sq.	7. R. to ad. Q. sq.
8. B. to K. R. 4th sq.	8. K. to K. B. sq.
9. B. to ad. K. B. 3d sq.	9. R. to ad. K. sq. chg.
10. B. to ad. K. 4th sq.	10. K. to K. Kt. sq.
11. R. to K. R. 4th sq.	11. K. to K. B. sq.

12. R. to ad. K. R. sq. giving check-mate

[1] Had he gone to Q. B. sq. he would have been check-mated in fewer moves.

[2] The pieces are now in precisely the same situation as at first, with this difference, that Black has the move. These preliminary moves, therefore, have been made for the purpose of transferring the move from the White to the Black.

[3] If he had interposed his Rook, you would have given him check-mate by playing Queen to King's Rook's 3d sq.

Method of Playing a King and Pawn against a King.

Situation.

White.	Black.
King at his 4th sq.	King at his 3d sq.
Pawn at ad. King's 4th sq.	
1. K. to Q. 4th sq.	1. K. to his 2d sq.
2. K. to ad. Q. 4th sq.	2. K. to Q. 2d sq.
3. P. to ad. K. 3d sq. chg.	3. K. to his 2d sq.
4. K. to ad. K. 4th sq.	4. If he were to play King

to his Queen's square, he would lose the game, as shown below; therefore he plays K. to his sq.

5. K. to ad. Q. 3d sq.	5 K. to Q. sq.

6. If you push the Pawn, he will play King to his own square, and then you must either play your King to adv. King's third square, giving stale-mate, or play your King away from the support of the Pawn; in either of which cases the game will be drawn.

If he had played differently at his fourth move he would have lost the game. Thus,

	4. K. to Q. sq.
5. K. to ad. Q. 3d sq.	5. K. to his sq.
6. P. to ad. K. 2d sq.	6. K. to K. B. 2d sq.
7. K. to ad. Q. 2d sq.	7. K. where he may.
8. P. to ad. King's sq. becoming a Queen.	

Example of a Smothered Mate.

Situation of the Pieces.

	K. at Q. Kt. sq.
K. at K. R. sq.	K. R. at its own sq.
Q. at ad. K. B. 3d sq.	Q. R. at Q. sq.
Kt. at ad. Q. 4th sq.	Q. R. P. at Q. R. 2d sq.
K. R. P. at K. R. 2d sq.	Q. Kt. P. at Q. Kt. 2d sq.
1. Q. to ad. K. 4th sq. chg.	1. K. to Q. R. sq.
2. Kt. to ad. Q. B. 2d sq. chg.	2. K. to Q. Kt. sq.
3. Kt. to ad. Q. R. 3d sq. chg.	3. K. to Q. R. sq.
4. Q. to ad. Q. Kt. sq. chg.	4. Q. R. takes Q.
5. Kt. to ad. Q. B. 2d sq. giving check-mate.	

The following curious problem was suggested by a near relative of one of our most illustrious naval heroes:

Situation.

K. at K. B. 4th sq.	K. at Q. Kt. sq.
Q. at ad. K. B. 2d sq.	P. at Q. B. 2d sq.
K. R. at Q. B. 4th sq.	P. at Q. B. 3d sq.
Q. R. at Q. R. 4th sq.	P. at Q. B. 4th sq.
K. B. at ad. K. B. 4th sq.	P. at Q. R. 2d sq.
Q. B. at ad. K. B. 3d sq.	P. at Q. R. 3d sq.
Q. Kt. P. at Q. Kt. 3d sq.	P. at Q. R. 4th sq.

White engages to check-mate Black with the *Knight's Pawn* in *eleven* moves, without taking any of the black pawns.

It may be done in *ten* moves, thus:

1. Q. to ad. K. sq. chg.	1. K. to Q. Kt. 2d sq.
2. Q. to ad. Q. B. sq. chg.	2. K. to Q. Kt. 3d sq.
3. K. B. to Q. 3d sq.	3 K to Q. Kt. 4th sq.
4. Q. B. to K. R. 4th sq.	4. K. to Q. Kt. 3d sq.
5. Q. B. to K. B. 2d sq.	5. K. to Q. Kt. 4th sq.
6. Q. R. to Q. R. 3d sq.	6. K. to Q. Kt. 3d sq.
7. K. R. to K. 4th sq.	7. P. to ad. Q. R. 4th sq. being his only move.
8. Q. to ad. Q. Kt. sq. chg.	8. K. to Q. R. 4th, his only move.
9. Q. B. to K. 3d sq.	9. P. to ad. Q. B. 4th sq. his only move.
10. P. to Q. Kt. 4th sq. giving check-mate.	

If Black had played otherwise at his sixth move, check-mate would have given in nine moves, thus:

White.	Black.
	6. P. to ad. Q. R. 4th sq.
7. Q. to ad. Q. Kt. sq. chg.	7. K. to Q. R. 4th sq.
8. K. R. to K. 4th sq.	8. P. to ad. Q. B. 4th sq. being his only move.
9. P. to Q. Kt. 4th sq. giving check-mate.	

Sarasin has an express treatise on the different opinions as to the origin of the word *schacchi*, whence the French *échecs* and our *chess* is formed. Menage is also very full on the same head. Leunclavius supposes it to come from *uscoches*, famous Turkish robbers; P. Sirmond from the German *schache*, theft, and that again from *calculus*. He takes *chess* to be the same with the *ludus latrunculorum* of the Romans, but erroneously. This opinion is countenanced by Vossius and Salmasius, who derive the word from *calculus*, as used for *latrunculus*. G. Tolosanus derives it from the Hebrew *scarch, volavit*, and *mat, mortuus;* whence *check* and *check-mate*. Fabricius says a celebrated Persian astronomer, one Schatrenscha, invented the game of *chess*, and gave it his own name, which it still bears in that country. Nicod derives it from *schecque*, or *xeque*, a Moorish word for lord, king, and prince. Bochart adds that *scach* is originally Persian; and that *scachmat* in that language signifies the king is dead. The opinion of Nicod and Bochart, which is likewise that of Scriverius, appears the most probable.

With regard to the origin of the game of chess we are much in the dark. Though it came to us from the Saracens, it is by no means probable that they were the original inventors of it. According to some, it was invented by the celebrated Grecian hero Diomedes. Others say that two Grecian brothers, Ledo and Tyrrheno, were the inventors; and that being much pressed with hunger, they sought to alleviate the pain by this amusement. According to Mr Irwin, it is a game of Chinese invention. During his residence in India he found that a tradition of this nature existed among the Brahmins, with whom he frequently played the game. But according to Sir William Jones, this game is of Hindoo invention. "If evidence were required to prove this fact," says he,[1] "we may be satisfied with the testimony of the Persians, who, though as much inclined as other nations to appropriate the ingenious inventions of a foreign people, unanimously agree that the game was imported from the west of *India* in the sixth century of our era. It seems to have been immemorially known in *Hindostan* by the name of *Cheturanga, i. e.* the four *angás*, or members of any army; which are these, *elephants, horses, chariots*, and *foot soldiers;* and in this sense the word is frequently used by epic poets in their description of real armies. By a natural corruption of the pure Sanscrit word, it was changed by the old Persians into *Chetrang;* but the Arabs, who soon after took possession of their country, had neither the initial nor final letter of that word in their alphabet, and consequently altered it further into *Shetranj*, which found its way presently into the modern *Persian*, and at length into the dialects of India, where the true derivation of the name is known only to the learned. Thus has a very significant word in the sacred language of the Brahmins been transformed by successive changes into *axidrez, scacchi, échecs, chess*, and, by a whimsical concurrence of circumstances, has given birth to the English word *check*, and even a name to the *exchequer* of Great Britain."

The game of chess has been generally practised by the

[1] *Asiatic Researches*, vol. ii. mem. 9.

greatest warriors and generals; and some have even supposed that it was necessary for a military man to be well skilled in this game. It is a game which has something in it peculiarly interesting. We read that Tamerlane was a great chess-player, and was engaged in a game during the very time of the decisive battle with Bajazet the Turkish emperor, who was defeated and taken prisoner. It is also related of Al Amin, the caliph of Bagdad, that he was engaged at chess with his freedman Kuthar at the time when Al Mamun's forces were carrying on the siege of that city with so much vigour that it was on the point of being carried by assault. In a battle between the French and English in 1117, an English knight having seized the bridle of Louis le Gros, and crying to his comrades, "The king is taken!" the king struck him to the ground with his sword, saying, "Ne sçais-tu pas qu'aux échecs on ne prend pas le roi?" Dr Hyde quotes an Arabic history of the Saracens, in which the caliph is said to have cried out, when warned of his danger, "Let me alone, for I see check-mate against Kuthar!" We are told that Charles I. was at chess when news were brought of the final intention of the Scotch to give him up to the English; but so little was he disturbed by this alarming intelligence, that he continued his game with the utmost composure, so that no person could have known that the letter he received had given him information of any thing remarkable. King John was playing at chess when the deputies from Rouen came to acquaint him that their city was besieged by Philip Augustus; but he would not hear them until he had finished his game.

The following remarkable anecdote we have from Dr Robertson in his history of Charles V. John Frederic, elector of Saxony, having been taken prisoner by Charles, was condemned to death. The decree was intimated to him while at chess with Ernest of Brunswick, his fellow prisoner. After a short pause, and making some reflection on the irregularity and injustice of the emperor's proceedings, he turned to his antagonist, whom he challenged to finish the game. He played with his usual ingenuity and attention; and having beat Ernest, expressed all the satisfaction that is commonly felt on gaining such victories. He was not, however, put to death, but set at liberty after five years' confinement.

Chess seems to have been in vogue at the court of Queen Elizabeth. Sir Walter Raleigh used to say that he did not wish to live longer than he could play at chess. Sir Charles Blount, afterwards Earl of Devonshire, having distinguished himself at a tilt, received from that princess a present of a chess-queen of gold enamelled, which he tied round his arm with a crimson riband. This favour from the queen produced a duel betwixt him and the Earl of Essex.

Charles XII. of Sweden was fond of the game; but he was not a successful player, in consequence of his making the king take too active a share in the contest. To this day a chess-king who advances too boldly into the fight is called Charles XII.

In the Chronicle of the Moorish Kings of Granada we find it related, that in 1396 Mehemed Balba seized upon the crown in prejudice of his elder brother, and passed his life in one continual round of disasters. His wars with Castille were invariably unsuccessful; and his death was occasioned by a poisoned vest. Finding his case desperate, he dispatched an officer to the fort of Salabreno to put his brother Juzuf to death, lest that prince's adherents should form any obstacle to his son's succession. The alcade found the prince playing at chess with an *alfaqui* or priest. Juzuf begged hard for two hours' respite, which was denied him; at last, with great reluctance, the officer permitted him to finish the game; but before it was finished a messenger arrived with the news of the death of Mehemed, and the unanimous election of Juzuf to the crown.

We have a curious anecdote of Ferrand, Count of Flanders, who, having been accustomed to amuse himself at chess with his wife, and being constantly beaten by her, a mutual hatred took place, which came to such a height, that when the count was taken prisoner at the battle of Bovines, she suffered him to remain a long time in prison, though she could easily have procured his release.

Two Persians had engaged in such deep play, that the whole fortune of one of them was gained by his opponent. He who played the white was the ruined man; and, made desperate by his loss, offered his favourite wife as his last stake. The game was carried on until he would have been check-mated by his adversary next move. The lady, who had observed the game from a window above, cried out to her husband to sacrifice his castle and save his wife.

The game of chess has undergone considerable variations since it was first invented. We have it on good authority, that among the eastern nations the piece now called the *queen* was formerly called the *vizir* or king's minister, and that the powers of the queen herself were but very small. The chess-boards used by Tamerlane were larger, and contained many more squares, than those at present in use. Carrera invented two new pieces to be added to the eight commonly in use. One of these, which he calls *Campione*, is placed between the king's knight and castle; the other, named *Centaur*, between the queen's knight and castle, has the move of the bishop and knight united. This invention, however, did not survive its author. In another of this kind the two additional pieces are called the *centurion* and *decurion;* the former situated between the king and his bishop, in its move the same with that of the queen, but only for two squares; the latter moves as the bishop, but only one square at a time. This, like the former, died with its inventor. The chess-board of Tamerlane was a parallelogram, having eleven squares one way and twelve the other. In the Memoirs of the late Marshal Keith, we find it related that he invented an amusement something similar to that of chess, with which the king of Prussia was highly entertained. Several thousand small statues were cast by a founder; and these were ranged opposite to each other as if they had been drawn up in an army, making the different movements with them as in real service in the field.

(J. D.)

CHESTER, an ancient city of England, capital of Cheshire; also a county in itself, and market-town. It is beautifully situated on the Dee, 164 miles N.W. from London. It consists of four main streets, and a great number of smaller ones. The whole of the town is surrounded by a wall 7 or 8 feet in thickness; on the summit of which is a walk with parapets on either side, much used as a promenade by the citizens, and which commands fine views of the surrounding country. The wall is very ancient, and is supposed to be of Roman origin. Chester was the Deva of the Romans, and was the permanent station of the twentieth legion. It occupied a very important position in the time of the lords marchers, and was their chief stronghold in the north. In two of the principal streets a very curious arrangement of the houses prevails, by which what are called the "rows" are formed, affording a promenade secure against the uncertainties of the weather. Fronting the pavement there is a row of inferior shops; on the top of these again

there is a broad paved walk, with a row of shops on the inner side, about 16 feet from the front of the lower row; the houses forming the second floor from the ground are then carried over the paved walk, and supported on pillars placed on the front of the lower row; and within this covered gallery are to be found the principal shops of the town. Numerous antiquities are from time to time brought to light, attesting the ancient origin of the place. A great many of the houses are built of timber, and some of them are most quaintly and elaborately carved. There is a very large training college for teachers, which is fast rising into repute. The cathedral is an old Gothic building containing some fine old carved oak, and some interesting monuments. The principal public buildings, besides those named, are the castle, the county-hall, the exchange, the linen, union, and commercial halls, the county jail, and the railway station; which latter is one of the largest and finest in the kingdom, and accommodates the traffic of six important railways. There are also public markets, an infirmary, and a house of industry. Chester has nine parish churches and two chapels of ease, besides numerous chapels belonging to the different dissenting bodies. There is a very fine race-course called the Roodee, just outside the town wall. The Chester race meeting has long ranked among the most important in the kingdom. There are very large works for the manufacture of white-lead, sheet-lead and pipes, and patent shot, giving employment to many hundred workpeople. Shipbuilding is also carried on to a considerable extent. Owing to the silting up of the mouth of the Dee, the shipping trade is not so brisk as it was at one time. Eaton-hall, the magnificent seat of the Marquis of Westminster, is close to the town.

The corporation consists of a mayor, ten aldermen, and thirty councillors. The borough has returned two members to parliament since 1543. Constituency in 1851, 2524. The Marquis of Westminster has the principal political influence. The assessed taxes yield annually L.1259; and the annual value of real property paying income tax is L.24,941. The population of the city in 1851 was 27,776, of whom 13,324 were males, and 14,442 females. There were 5173 inhabited houses, 196 uninhabited, and 35 building. There are weekly markets on Wednesdays and Saturdays, and several very large horse, cattle, and cheese fairs, during the year.

CHESTERFIELD, a municipal borough and market-town of England, county of and 21 miles N. of Derby, on the rivulets Rother and Hipper. It has manufactures of lace, cotton, silk, carpets, hosiery, earthenware, and machinery. The church is an elegant and spacious edifice of the thirteenth century, with a remarkable twisted spire 230 feet high. There are several dissenting chapels, a free grammar and other schools, town-hall, prison, assembly-rooms, theatre, dispensary, mechanics' institute, and savings-bank. In the vicinity are coal, iron, and lead mines. The Chesterfield canal extends from the town to the Trent near Stockwith, 46 miles. The town is governed by a mayor, four aldermen, and twelve councillors. Pop. (1851) 7101.

CHESTERFIELD, *Earl of.* See STANHOPE.

CHESTER-LE-STREET, a village of England, county of Durham, near the Wear, 6 miles N. of Durham. Pop. (1851) 2580. Its Saxon name was Cuncaestre; and from 882 to 995 it was the seat of the episcopal see of Durham. The church, which was formerly collegiate, is a fine old Gothic structure with a tower at its W. end, surmounted by an elegant spire 156 feet high. The manufactures are unimportant, the inhabitants being chiefly employed in the coal mines of the neighbourhood. Lumley castle, the seat of the Earl of Scarborough, is in the immediate vicinity.

CHESTNUT. See HORTICULTURE; PLANTING; TIMBER.

CHEVAL-DE-FRISE, generally used in the plural, *chevaux-de-frise,* a military engine consisting of a large piece of timber traversed with pikes five or six feet long, and pointed with iron; used to defend a passage, stop a breach, or form a retrenchment against cavalry. Chevaux-de-frise were first employed at the siege of Groningen in 1658. The term is French, and literally signifies a *Friesland horse,* the term having been applied either from some conceived analogy between the appearance of the shaggy horses of the country and that of the instrument, or more probably because it was invented in Friesland.

CHEVALIER (from *cheval,* a horse), a French term signifying a knight. In heraldry it denotes a horseman armed at all points, a *cataphract.*

CHEVERON and CHEVERONEL. See HERALDRY.

CHEVIOT HILLS, a mountain range extending from NE. to SW. between England and Scotland, partly in Northumberland and partly in Roxburghshire, but mostly in the former. They afford excellent pasture for sheep, and give name to a valuable and peculiar breed of that animal. The Cheviot peak, 2684 feet high, is in Northumberland, on the borders of Roxburghshire, 8 miles S.W. of Wooler. These hills were the scene of many bloody contests between the English and Scotch, one of which is recorded in the celebrated ballad of "Chevy Chase."

CHEVREAU, URBAN (1613–1701), a learned writer, was born at Loudun in Poitou. He early distinguished himself in the study of the belles-lettres, and was appointed secretary to Queen Christina of Sweden. After spending some time at the court of Denmark, he was employed as counsellor by Charles Louis, the elector palatine; and on the death of that prince he returned to France, where he became tutor to the Duke of Maine. His principal work, the *Histoire du Monde,* Paris, 1686, 2 vols. 4to, he is alleged by some to have taken without acknowledgment from the *Theatrum Universum* of Christian Mathias; but this charge has not been substantiated.

CHEYNE, DR GEORGE (1671–1742), was born in Scotland, and educated under Dr Archibald Pitcairne. After his graduation he settled in London, where he soon became known by the publication of his *Theory of Fevers,* and also of a work *On Fluxions.* In the former of these he advocated the mechanical theory of secretion, in accordance with the doctrines which he had imbibed from his master. Having been twice the victim of an excessive corpulency, which he twice succeeded in subduing by means of vegetable diet, he wrote a book entitled *The English Malady,* in which he has given a variety of curious details in regard to his own treatment, and the dietetic treatment of diseases in general. He had also discussed the same subject in his *Essay on Health and Long Life.* Besides these, he published in early life a treatise on the *Philosophical Principles of Natural Religion,* which was dedicated to the Earl of Roxburghe; and his later writings are uniformly pervaded by a genial spirit of piety and benevolence. He died at Bath, whither he had retired for his health, in 1742.

CHIABRERA, GABRIELE (1552–1637), a famous Italian poet, born at Savona, and educated in the Jesuits' college at Rome. He received invitations from Urban VIII., and many of the Italian princes, to fix his residence in their capitals, but preferred to prosecute the study of poetry in his native place. He wrote four epics, entitled *La Gotiade o delle guerre de Goti, La Firenze, L'Amedeida,* and *Il Ruggiero;* a tragedy, entitled *Erminia,* besides several comedies, dramas, and smaller poems. His works have been frequently collected. For a critical estimate of Chiabrera, see POETRY.

CHIAPA, a state of Mexico. See MEXICO.

CHIAPA DE LOS INDOS, the largest town in the above state, situated in a valley near the banks of the river Tabasco, 20 miles N.W. of Ciudad Real. The inhabitants, amounting to about 15,000, are chiefly Indians, but they are reported to be rich. A great quantity of sugar is

raised in the district. The heat is excessive during the day, but the nights are cool. This place enjoys many privileges, and is rising into importance.

CHIARAMONTE, a town of Sicily, province of and 32 miles W. from Syracuse. It is regularly built, with broad and straight streets. The view from the Capuchin convent is one of the finest in Sicily. The environs produce excellent wine. Pop. 7000.

CHIARI, a town of Lombardy, province of and 12 miles W. from Brescia. It has several churches, an hospital, and considerable manufactures of silk and leather. Pop. 8000.

CHIARI, *Giuseppe* (1654–1727), an Italian painter, the disciple of Carlo Maratti. He was employed in decorating various churches and palaces at Rome.

CHIAROSCURO. See CLARO OBSCURO.

CHIAVARI, a maritime town of the kingdom of Sardinia, capital of a province of the same name, in the division of Genoa, situated on the Gulf of Rapallo, at the mouth of the Sturla, 23 miles E.S.E. of Genoa. Pop. 11,000. The town is well built and flourishing, is surrounded by cultivated hills, and in the vicinity there are many handsome villas. It has many fine edifices, hospital, public library, manufactures of lace and silk twist, and an anchovy fishery. In the neighbourhood there are marble and slate quarries.

CHIAVENNA (*Clavenna*), a small town of Lombardy, province of Valteline, on the right bank of the Maira, 20 miles N.W. of Sondrio. It is a place of considerable trade, being situated at the junction of the great roads over the Splügen and Septimer, between Germany and Italy. Its principal manufacture is silk. Pop. 3500.

CHIAUSI, among the Turks, officers employed in executing the viziers, pashas, and other high functionaries. The orders for this purpose are sent by the grand signior wrapped up in a black cloth; on the reception of which the chiausi immediately perform their office.

CHICAGO, a city of the state of Illinois, North America, situated on S.W. shore of Lake Michigan, at the mouth of the Chicago river. Lat. 42. 52. 20. N.; Long. 87. 35. W. Chicago is the most remarkable city in the states for the rapidity of its increase. In 1830 it was a mere trading station, and in 1840 had only 4470 inhabitants. In 1850 these had increased to 27,620, and in 1855 amounted to no less than 80,000. The city borders on a rich and beautiful prairie extending in different directions for many miles, finely diversified by groves and strips of timber, gardens, and villas. Though the site is low and level, being only a few feet above the lake, there are no marshes or wet lands; and the agitated waters of the lake ensure a salubrious atmosphere. The river Chicago consists of two branches, which unite about two miles from its mouth, forming an extensive and commodious harbour. The city extends along the shore of the lake for about a mile, and inland beyond the bifurcations of the river. The bar at the entrance has been much reduced, and piers have been erected to prevent the accumulation of sand, so that the depth is now sufficient for the largest lake craft and steamers. Chicago is the natural entrepot for the trade between the flourishing state of Illinois and the vast regions watered by the great lakes; and by means of an extensive system of canal and railway communication its commerce reaches from the Atlantic to the Mississippi. Of this system the most important features are—the Illinois and Michigan canal 100 miles in length, extending from the lake to the Illinois river at La Salle, and forming an outlet for the rich products of Kentucky, Missouri, Iowa, and Illinois; two lines of railroad round the bend of lake Michigan, thence continuous to the sea-board at Boston and New York, uniting also with the Indiana and Ohio railroads; lines to the Mississippi river at Galena, Rock Island, Quincy, Alton, Cairo, &c. There are 12 main trunk railways, 2646 miles in length, already in operation or to be completed by 1856, terminating at Chicago, and nearly each trunk has one or more branches; these are, the Michigan Central to Detroit, 208 m.; Michigan Southern to Toledo, 245 m.; Chicago and Fort Wayne, 180 m.; Illinois Central to Cairo, 351 m.; Chicago and Mississippi to Alton, 280 m.; Chicago, Aurora, and Central Military Tract to Quincy, 220 m.; Chicago and St Charles Air Line to Galena, 160 m.; Chicago and Galena to Dubuque, 200 m.; Illinois and Wisconsin to Fond du Lac, 180 m.; Chicago and Rock Island, 180 m.; Chicago and Cincinnati, 280 m.; Lake Shore to Milwaukee, 90 m. In 1842 the value of property in Chicago was assessed at $2,325,240, and in 1852 at $12,035,037. The arrivals of vessels at this port during 1852 were, 366 paddle and 181 screw-steamers, 20 barques, 257 brigs, and 1172 schooners, with an aggregate burden of 545,491 tons. Chicago in 1853 had 7627 dwelling-houses, 1184 stores and places of business, 54 schools, 61 churches, and 196 manufactories.

CHICANE, or CHICANERY, in law, an abuse of judiciary proceedings, tending to delay the cause, puzzle the judge, or impose on a party.

CHICHESTER, a municipal and parliamentary borough, episcopal city, and market town of Sussex, is situated at the foot of a small spur of the South Down Hills on the widest part of the plain to which it gives name. N. Lat. 50. 51.; W. Long. 0. 47. It is distant about 60 miles S.W. from London, and 14 N.E. from Portsmouth. Chichester is a corruption of Cissancester, the castle or stronghold of Cissa, an Anglo-Saxon chief who rebuilt the town after it had been destroyed by his father Ælla. It occupies the site of Regnum, an old military station of the Romans, by whom it is believed the walls which have a circuit of about a mile and a half were originally erected. The town is well-built, and consists of four principal streets, which meet at right angles at a central octagonal cross, reputed to be one of the finest structures of the kind in Great Britain. Of the public buildings most remarkable, there is the cathedral, which is 407 feet in length, 150 in breadth, and is note-worthy as having double aisles; the church of St Paul, a modern Gothic edifice; the guild-hall; the corn-exchange; the market-house; the infirmary; and the museum of the philosophical society. In the cathedral are a number of ancient and curious monuments, besides nine by Flaxman, one of which is in memory of the poet Collins, who was a native of the city. The diocese of Chichester includes the whole county of Sussex except a few parishes which are peculiars, and comprises nearly 300 benefices. The palace of the bishop (whose annual income is L.4220) is in the city of Chichester. The Independents have two places of worship in Chichester, which also possesses National, British, and infant schools for boys and girls. The blue-coat school (with an annual income of L.1300) boards and educates 28 boys. In addition to these there is a grammar-school, founded by Bishop Story in 1497.

Chichester communicates with the sea by means of a short canal. Its registered shipping amounted in 1852 to 38 vessels, with an aggregate of 1806 tons. Its coasting and foreign trade engaged in that same year 450 vessels, with an aggregate of 22,980 tons. Chichester returns two members to parliament. Its registered electors number 757. The city is governed by a municipal corporation, consisting of 6 aldermen and 18 councillors, from among whom the mayor is chosen. Pop. 8662.

CHICKEN-POX, a mild contagious eruptive disease, generally appearing in children. It rarely attacks the same individual more than once.

CHICORY, or SUCCORY, the wild endive, or *Cichorium Intybus* of Linnæus, is a plant that grows wild on calcareous soils in England and most parts of Europe. It was formerly raised to some extent in England as a medicinal herb, but is now almost exclusively employed as a substitute for

coffee. For this purpose the roots are kiln-dried and ground to powder in a mill. Though largely used as a beverage, chicory wants the essential oil and rich aromatic flavour of coffee. It forms, however, a not unpleasant beverage; and its cheapness recommends it to the poor. The quantity raised in England in 1850 is said to have amounted to about 12,500 tons. The mixture of chicory with coffee has given occasion for several special enactments; but by a minute of treasury issued Feb. 25, 1853, the question was finally settled, and the sale of coffee mixed with chicory was legalized—under the proviso, however, that each parcel containing such compound be labelled "Mixture of Coffee and Chicory."—See M'Culloch's *Dict. of Commerce*, Lond. 1854.

CHICLANA, a town of Spain, 13 miles S.E. from Cadiz, containing the residences of many of the Cadiz merchants. Near it is *Medina Sidonia*, supposed by some to be the Phœnician *Asidon;* and about 5 miles S. is the field of Barossa, where the Anglo-Spanish army headed by Sir Thomas Graham (afterwards Lord Lynedoch) defeated the French under Marshal Victor, March 5, 1811. Pop. about 6000.

CHIEF, a term signifying the head or principal part of a thing or person. The word is formed from the French *chef*, from κεφαλή, *caput*, head.

Chief, in *Heraldry*, is that which occupies all the upper part of the escutcheon from side to side. *In chief* imports something borne in this part. See Heraldry.

CHIEFTAIN, the captain or chief of any class, family, or sept. Thus the chieftains of the Highland clans were the patriarchal and feudal heads of their respective clans.

CHIERI, a pleasantly situated and tolerably well built town of Italy, kingdom of Sardinia, Piedmont, province and eight miles S.E. of Turin, on the declivity of a hill, at the foot of which flows a small stream. It has manufactures of silk, cotton, linen, and woollen goods, and about 14,000 inhabitants.

CHIETI, an important and flourishing city of Naples, capital of the province of Abruzzo Citeriore, situated on a hill near the Pescara, 40 miles E. of Aquila. It is the seat of an archbishop, and has a fine cathedral, college, hospital, several convents, and a handsome theatre. Chieti commands a fine view of the surrounding country and the Adriatic, from which it is six miles distant. Pop. 14,000. Its chief productions are corn, wine, oil, silk and woollen goods, &c. It occupies the site of the ancient *Teate*, which gave name to an order of monks in the sixteenth century. It has remains of a large theatre, two temples, a gateway, and mosaic pavement.

CHIGI, Fabio, afterwards Pope Alexander VII., was born at Sienna in 1599. Having been early sent to Rome, he formed a friendship with the Marquis Pallavicini, who recommended him to Pope Urban VIII., and procured his appointment as inquisitor at Malta. He was next sent as vice-legate to Ferrara, and afterwards as nuncio into Germany, where, at the conference of Munster, he had abundant opportunity for displaying his genius for intrigue. Cardinal Mazarin cherished a secret resentment against Chigi, who was soon afterwards made cardinal and secretary of state by Innocent X.; but this resentment was wisely sacrificed to political views. Chigi, after his elevation, laid aside the mask of sanctity, and indulged openly in luxury and voluptuousness. There is a volume of his poems still extant; and the plan of the college Della Sapienza, which he finished and adorned with a fine library, sufficiently attests his fine taste in architecture.

CHIHUAHUA, a state of Mexico. See Mexico.

Chihuahua, a town of Mexico, capital of the state of the same name, lies in a beautiful valley opening towards the north, and hemmed in on the other sides by arms of the Sierra Madre, 4640 feet above the level of the sea. Lat. 28. 38. N., Long. 106. 30. W. The city is regularly built, and the streets are wide and clean, with many handsome and convenient houses, plentifully supplied with water, which is brought to the town by an aqueduct three miles in length. The grand square, three sides of which are occupied by public edifices and stores, and the fourth by the cathedral, has its spacious area adorned with fountains, walks, and benches and pillars of white porphyry. Pop. from 12,000 to 15,000. Near it are many rich but unwrought mines.

CHILBLAIN, a tumour or sore produced by exposure of the extremities to cold; accompanied with inflammation and itching, and sometimes with pain, and even with ulceration. Chilblains are not unfrequently induced by warming the hands and feet too suddenly after exposure to great cold; and hence proximity to the fire should be avoided until the circulation be properly restored. They are generally relieved by moderately stimulating applications; as for instance equal parts of solution of acetate of ammonia, or of vinegar and spirits of wine, or of oil of turpentine and soap liniment. An aqueous solution of alum also is frequently very efficacious, especially if applied after steeping the part affected in hot water.

CHILDERMAS-Day, or *Innocents' Day*, an anniversary held by the Church of England on the 28th of December, in commemoration of the massacre of the children of Bethlehem by order of Herod.

CHILE.

The republic of Chile occupies that long strip of land which lies on the south-western side of South America, extending from S. Lat. 24. to 55. 59.; and from W. Long. 69. to 72. It is bounded W. by the Pacific Ocean, and E. by the Andes, by which it is separated from the Argentine Confederation. On the N. Chile is separated from Bolivia by the extensive desert of Atacama; and it extends southwards to the extreme limits of that archipelago which embraces all the islands between Chiloë and the Straits of Magellan. Reckoning its length from the desert of Atacama to Cape Horn, it comprehends 36 degrees of latitude. Its average breadth is only 150, and where greatest, not more than 210 geographical miles. The superficial area of Chile is computed at 218,925 English square miles, being about 3195 miles more than that of France and Belgium together. Except where the Andes are intersected by ravines, which frequently expand into vales or plains fit for cultivation, these mountains, with their parallel ranges and spurs, occupy a great part of its area.

Physical appearance.

Under the dominion of Spain, the *Capitania-general* of Chile extended from S. Lat. 24. to Cape Horn; but as no settlements were actually formed beyond S. Lat. 44., the length of the Spanish possessions may be estimated at 1400 English miles. The ranges of the Andes, which, from their height and excessive coldness, are uninhabitable, cover nearly one-third of the surface of Chile. Between the Andes and the sea there are two parallel ranges, which decrease in elevation towards the coast, and are connected by several smaller ridges. Many deep basins are thus formed, some of which are filled with water from the melted snows of the Cordilleras; while in others the waters have found an outlet, and have left a fertile table-land, in which pasture may be obtained when the great droughts have destroyed the herbage in the less elevated districts.

Chile.

From the foot of the lower range of the Andes the land gradually descends towards the sea, but more precipitously near the shore, which is skirted by a comparatively low tract of country. Even this district, however, is crossed by numerous spurs from the Andes, and presents a series of barren mountain plains, intersected by deep *quebradas*, or fissures, which, during the melting of the snows in summer, are watered by large and rapid streams, and form the only cultivated districts in the country. As rain rarely falls in Northern Chile, except in the two or three winter months, and as the dews are light, the districts between these fissures are almost destitute of vegetation. In the Andes, which separate Chile from the Argentine Republic, there are several passes that can be traversed in safety in summer. The most frequented are those of Dehesa, near Tupungato, to the E. of Santiago; Copiapo, in Atacama; Colgüen, in Coquimbo; the Patas, in Aconcagua; and the Portillo Uspallata.

Geology.

No part of South America has had its geology so well investigated as Chile. Its stupendous mountains, rising in some places to the elevation of 23,900 feet above the level of the sea,—its numerous volcanoes, three of them generally in a state of active eruption,—and its very peculiar geological structure,—make it, with the exception of Peru, the most interesting part of South America.

It may be said that in Chile various geological phenomena are still in active operation. The grand range of the Cordilleras has suffered the most violent rendings and movements both upward and downward. There is the strongest evidence for believing that the parallel ridges which compose the Cordilleras were thrown up at different periods, that they afterwards subsided some thousand feet, were then brought up by a gradual movement, and again, during the old tertiary period, subsided to nearly their previous elevation, to be afterwards raised to their present level by a slow and often interrupted movement.

The Cordilleras and the Andes, though often used indiscriminately, are, in fact, as in Peru, different chains of mountains, running nearly parallel to each other. The former is termed in the south Cordilleras de la Costa (Cordilleras of the Coast), and between it and the Andes are extensive plateaux, which gradually sink in elevation from Central Chile to the S. For instance, Santiago the capital is at an elevation of 1830 feet above the level of the sea; whilst Rancagua, 63 miles further south, is 1558 feet; and Talca, 165 miles still further south, is only 311 feet above the sea.

Although the plain between the southern chains alters so rapidly in elevation, yet the northern chain from Aconcagua to Atacama, rising to a mean elevation of nearly 15,000 feet, displays throughout little variety in its forms; but further S., in S. Lat. 33., it assumes a different appearance, new rocks and formations showing themselves on its surface. Towards Lat. 33., volcanic masses of a modern period are first met with; cones springing up into points, covered with snow and ice, the fires of whose craters have only lately become inactive. There, rising to an elevation of 23,600 feet, is the stupendous mountain of Aconcagua, which has been generally considered as a volcano; but recent observation has ascertained that this is not the case. Although its top is far above the line of perpetual snow, yet frequently no snow is visible for many months on its surface. This is caused no doubt by the extreme dryness of the air. Further S. are Tupungato, 23,000 feet high; Juncal, 19,900; the Maipo Volcano, 19,000; and El Portillo, with its immense escorias, and the volcano of San José, each rising to the height of more than 18,000 feet above the level of the sea.

The whole chain of the Cordilleras, from Tierra del Fuego to Mexico, is penetrated by volcanic orifices, and those now in action are connected in great trains. In the Chilean range there are 23 volcanoes, some of them very ancient, without craters; some with craters, but quite extinct; others in the condition of solfataras; and others, such as Osorno, Villa Rica, and Antuco, in the S., and San José in the province of Santiago, in occasional and fierce action.

Chile.

The average width of the country between the Cordilleras and the sea is from 80 to 100 miles. It is crossed by various spur-like chains: the greater part of which, lying south of S. Lat. 31., range nearly N. and S.; but in the northern parts they run in every direction. The cultivated region of Chile may be considered to be between the River Biobio and the port of Coquimbo, that is to say, between seven degrees of latitude; and as the mean width is about two degrees of longitude, consequently the surface is equal to 7350 square Chilean leagues of 25 to a degree, from which must be deducted the part occupied by the Cordilleras of the Andes, forming at least one-third of this surface; therefore the actual part susceptible of cultivation is reduced to 4900 square leagues. However, several of the valleys of Huasco and Copiapo produce considerable quantities of fruit and vegetables.

There is the most positive evidence of the recent elevation of the most northern part of Chile from about 45° S. Lat.; and, indeed, a similar elevation can be traced on to Peru to a distance of about 2000 geographical miles. As the land is generally steep, shells are seldom found at a greater distance than three leagues from the coast; but the pirena, astarte, gryphæa, and turritella have been frequently found at an elevation of 12,000 feet above Huasco and Copiapo. The marks of sea action are evident at a distance of 30 to 40 miles inland, by ancient beaches, and successive and perfectly formed terraces. In Chiloë, shells are found at an elevation of 350 feet; at Concepcion, 625; at Valparaiso, 1300; and at Coquimbo, 252 feet. At Caldera, the port of Copiapo, the present line of the railway, to an elevation of 300 feet above the level of the sea, is cut through thick beds of shells of existing species.

On examining with attention the northern part of Chile, it is seen that there have been five ascensional movements of the coast. Round the Bay of Coquimbo the surface rises like an amphitheatre in five very marked stages, forming concentric terraces. The first terrace, a mile wide, rises to an elevation of about 23 feet,—it consists of sand-duns, and towards the town of Serena, of salt and fresh water marshes, with shells similar to those found on the beach. A steep escarpment leads to the second terrace, about 70 feet above the level of the sea, on which the town of Serena is built, the upper part covering the third terrace at an elevation of 120 feet. The fourth terrace, which is narrow, rises 182 feet above the third; and a steep escarpment leads to the fifth, or upper terrace. Above the town, it is entirely composed of immense masses of rounded shingle, and stretches along the coast, and inland to a distance of 11 miles. About 2 miles from Port Coquimbo, this fifth terrace sinks about 100 feet below the surrounding level; and a few inches below the sandy surface, there is a thick stratum of calcareous matter filled with shells, which forms an excellent building-stone and good lime. On advancing northward, the same terraces are observed. On going up the valley of Huasco to the town of Ballenar, about 37 miles inland, the five terraces are perfectly defined, composed of gravel aggregated together in a matrix of clay. In the neighbourhood of Valparaiso the elevation of the coast is very apparent. On the S. side of that town are numerous headlands, covered with broken shells to an elevation of 230 feet; and even at an elevation of 557 feet very comminuted shells are found, similar to those which exist in the neighbouring sea. The principal species are the patellæ, trochus, crepidulæ, and concholepas, some of which are occasionally to be found at an elevation of 1300 feet.

North of Valparaiso, near to Concon, are immense beds

of the mesodesma-donaciforme, which supply lime for the town and many leagues round. The same fossil shell is found in such abundance near Coquimbo, to the elevation of 80 feet above the sea, that an English smelting establishment at Herradura, $2\frac{1}{2}$ miles from the port of Coquimbo, has frequently purchased nearly 3000 quintals in a week for the purpose of making lime; and at Sangoy, where the same English company has another smelting establishment, the quantity is so great that it is collected and delivered into the works at the low rate of two dollars per cajon of 64 quintals.

From the indications of the action of the sea at different elevations, we may suppose that the process of elevation has been interrupted by long periods of comparative rest; and from the similarity of the distant terraces, no doubt the periods were synchronous over wide spaces of the coast.

Earthquakes.

Chile is very subject to severe earthquakes. They manifest themselves by a quick horizontal, vertical, and sometimes by a sort of rotatory vibration. They generally occur in a linear direction; but at other times partly in circles or in long ellipses. The earthquakes of 1835 and 1851 were of the latter description, the vibrations being propagated with decreasing intensity from a centre towards a circumference. It is affirmed by all miners, that the most severe shocks are not felt in deep mines, although the loud rumbling sound, like a heavy cart passing rapidly along a narrow street, which precedes the shock, is distinctly heard.

It is a very general opinion, that the atmospheric pressure is disturbed on the days when earthquakes occur; but the result of seven years' barometric observations in Chile refutes this opinion, as we have observed the horary variation of the barometer to be rarely affected either before or after earthquakes. Changes of the weather, however, generally succeed earthquakes. Immediately after the great earthquake of February 1835, torrents of rain fell in Concepcion, although in the midst of summer, when rain is nearly unknown. Experience shows that about two desolating shocks may be expected in a century. The intensity of the shocks is supposed to be increased according to the time intervening between them, and the danger to be greatest when the volcanic vents are closed. Although they appear to be simply dynamic phenomena of motion, yet in Chile they have suddenly elevated whole districts above the ancient level. By the earthquake of February 1835, the Isle of Santa Maria was uplifted, the southern end 8, the central part 9, and the northern end 10 feet; but both it and Concepcion subsided a few weeks afterwards, and even lost part of their previous elevation. The sea is generally much agitated during and for a short time after the shocks. During the earthquake which destroyed Concepcion and nearly all the towns in the S. of Chile, two great waves rolled over the town of Talcahuano, and the small penal establishment of Juan Fernandez was nearly washed away; the deep sea, close in shore, was dry for a few moments, and smoke burst from the surface of the water. During a very smart earthquake at Coquimbo, in November 1849, the sea retired about 150 yards, and then rolled back about 12 feet high. An English ship, anchored in 7 fathoms water, in the neighbouring bay of Herradura, nearly touched the bottom from the receding of the sea, which afterwards rolled in like a bore, and the water continued to ebb and flow for an hour and a half after the shock.

Lakes.

The appearance of the country is agreeably diversified by lakes, which are especially numerous in the southern provinces. In some of these, situate near the coast, such as Bacalemu, Cahuil, Vichuquen, and Bollenica, the water is brackish; but in Ranca, Villarica, and the lakes of the interior, it is quite fresh. They generally abound with fish; and are frequented by numerous varieties of aquatic birds. In some districts, and particularly in the Cordilleras, there are valuable thermal springs. The most celebrated for their medical virtues are those of Colina, Cauquenes, Panimavida, and Chillan.

Rivers.

Chile, particularly in its southern division, is abundantly supplied with rivers and streams, which, however, from the nature of the surface, have generally a short and rapid course, and are navigable only for a few miles from their mouths. The Biobio has a course of nearly 200 miles, and though not less than 2 miles in breadth at its mouth, is too shallow for large vessels to enter. It is navigable for river craft as far as Nacimiento, about 100 miles from the sea. The Maule is navigable for river barges for about 20 miles; and the Aconcagua, the Cauten, and the Callacalla (which last is deep enough for large vessels to enter), are considerable streams. All the navigable rivers flow through that part of Chile which is S. of the Maipù, where the rains fall abundantly. They are very rapid, owing to the declivity of the country, which renders them easily available for irrigation; and thus large tracts, which would otherwise be barren, are rendered rich and fertile.

The following table gives the length of the principal rivers, and the provinces through which they flow:—

Names of Rivers.	Province.	Length of course.	Falls into
Biobio	Concepcion and Arauco	94 leagues	Pacific Ocean
Aconcagua	Aconcagua	76 ...	...
Cauten, or Imperial	Arauco	68 ...	...
Maule	Maule	64 ...	...
Cachapoal	Santiago	62 ...	Topocalma
Itata	Concepcion	60 ...	Pacific Ocean
Mataquito	Talca	60 ...	...
Topocalma, or Rapel	Colchagua	56 ...	...
Valdivia, or Callacalla	Valdivia	55 ...	...
Coquimbo	Coquimbo	54 ...	...
Cruces	Valdivia	52 ...	Valdivia
Maipù	Santiago	50 ...	Pacific
Copiapo	Atacama	50 ...	...
Huasco	...	50 ...	...
Ligua	Aconcagua	48 ...	...
Tolten	Valdivia	48 ...	...
Laja	Concepcion	44 ...	Biobio
Loncotoma	Aconcagua	40 ...	Pacific
Bueno	Valdivia	40 ...	...
Limari	Coquimbo	38 ...	...
Mapocho	Santiago	38 ...	Maipù
Vergara	Arauco	36 ...	Biobio
Juncal	Atacama	34 ...	Pacific
Tabolevo	Arauco	30 ...	Biobio

Climate.

In a country like Chile, extending from the tropic of Capricorn to within twelve degrees of the Antarctic circle, and presenting great differences of elevation, considerable variety of climate may be anticipated. Omitting the cold and thinly inhabited region to the extreme south, and beginning with the province of Chiloë, Chile may be divided into three regions, which may be distinguished as the wet region, the corn and wine region, and the dry, or mineral region. The wet region comprehends Valdivia, Arauco, and Chiloe, and is so much exposed to excessive rains, that in Chiloë it is frequently necessary to dry the wheat and barley crops by artificial means. The corn and wine region embraces the eight provinces between Arauco and Coquimbo, and in these rain falls in the months of June, July, and August, with more or less abundance as they approach the S. In April, May, September, and October, showers are more rare and uncertain. In the provinces S. of Talca, the amount of rain being insufficient for agricultural purposes, it is necessary to resort to irrigation. The dry, or mineral region, including Coquimbo and Copiapo, is very warm, and receives only four or five showers in the whole course of the year. These, however, are so fertilizing, that an almost instantaneous change takes

Chile.

place in the appearance of the country. In the neighbourhood of the Andes, as well as towards the S., the atmosphere is often cooled by nocturnal frosts. Spring commences in September, summer in December, autumn in March, and winter in June.

The mildness and salubrity of the climate is unsurpassed by that of any other country. The following table shows the average rate of mortality in the different provinces. Most of the observations are confined to the year 1848, but some of them embrace also the average of other years:—

Provinces.	According to observations in	Deaths.
Atacama	1848	1 in 60·6
Coquimbo	1848	1 „ 73·7
Aconcagua	1848	1 „ 60·3
Valparaiso	1848, 1849	1 „ 35·7
Santiago	1848, 1849	1 „ 31·8
Colchagua	1848	1 „ 43·1
Talca	1848, 1850	1 „ 43·2
Maule	1844, 1848, 1849	1 „ 49·9
Nuble	1848	1 „ 80·5
Concepcion	1844–6–7–8–9–50	1 „ 70·1
Valdivia	1848	1 „ 160·4
Chiloë	1848, 1849	1 „ 42·9

From this table it will be seen that Valdivia, in a sanitary point of view, is the most favourably situate of all the provinces; and that Valparaiso and Santiago, in which are the two largest cities, are the worst. The following table shows the average number of births and deaths in the provinces of Valparaiso, Santiago, Talca, Maule, and Chiloë, during the several months of the year:—

Months.	Births	Deaths.
January	1851	1266
February	1609	1011
March	1984	986
April	1829	938
May	2247	1022
June	1539	1099
July	1556	1166
August	1773	1193
September	2614	1166
October	2576	1238
November	2387	1284
December	2287	1402

From this table we learn that the deaths are most numerous in December, November, and January; and fewest in February, March, and April.

Constitution.

The constitution according to which Chile is at present governed was adopted on the 25th of May 1833. By that constitution the sovereignty is declared to reside in the people; but the exercise of its functions is delegated to three distinct powers—the legislative, the executive, and the judicial. The legislative power is committed to the National Congress, which consists of the Chambers of Deputies and Senators. The Chamber of Deputies comprises 57 members, who are elected each for a period of three years, in the proportion of one deputy for every 20,000 inhabitants in the electoral districts. If, as is the case in some of these, the population does not amount to the above-named number, but exceeds 10,000, the same electoral privilege is still conferred upon them.

Suffrage.

According to the eighth article of the constitution, all who exercise the right of suffrage must be twenty-one years of age if married, and twenty-five if unmarried. They must be able to read and write. They must possess immoveable property, or an adequate capital invested in some branch of industry; or they must follow some employment, and the value of these required to constitute an elector shall be declared decennially. By the last decennial law, promulgated in 1849, it is declared that the value of immoveable property must not be less than L.200 in the provinces of Santiago and Valparaiso, that the capital in circulation must amount to at least L.400, and the annual income to L.40. In all the other provinces, the value of immoveable property must not be less than L.100, the capital in circulation at least L.200, and the annual income not under L.20.

The Senate is composed of twenty members, who are chosen by a select body of the electors of each province; every one of whom must have a clear annual income of L.110. This body must be equal to three times the number of deputies representing any particular province; and its members are chosen by the electors themselves from their own number. At electoral contests, the result of the proceedings is transmitted to a body known as the conservative committee, which sits in the capital. After having examined these proceedings, and satisfied themselves that everything has been conducted in accordance with legal forms, they declare the successful candidate.

A senator's term of office is nine years. The house of this branch of the legislature is renewed by thirds. In each of the first two periods of three years seven new senators are chosen, and in the last only six.

Chambers.

The functions of the Chamber of Deputies and of the Senate are partly discharged in concurrence with each other, and partly exclusively. The former body alone possesses the power of accusing the higher officers of government before the Senate for various political offences. It originates all money bills, and propositions relating to the recruiting of the military force of the country. The Senate alone has the right of pronouncing judgment on those public functionaries against whom accusations have been brought by the members of the Chamber of Deputies. It confirms all the ecclesiastical nominations. In certain cases it gives or withholds its consent to the acts of the executive.

In all the other proceedings of the legislature the concurrent voice of the two houses is necessary. Laws for the benefit of the country may originate with either body. When a law has been rejected, or the veto of the president put upon it, it cannot be brought again before the Chambers till the following year. The period during which the Congress sits is limited to the three winter months; but when the affairs before it are of such a nature as to render additional deliberation necessary, the session may be prolonged by the president for fifty days. On the day before the regular session closes, the senators elect seven of their number to form the conservative committee, which replaces the Congress during the period of its prorogation. The duties of this body are, to observe the conduct of the president; to exercise in certain cases conjoint powers with him; and, generally, to see that the laws are duly obeyed.

President

The executive power is committed to the President, who is the supreme chief of the nation and of the administration. He is elected with the same formalities as the senators, and by electors chosen in a similar manner. The office is held for a period of five years; but the president whose term has expired may be immediately re-elected for the same period. On the termination of his second term of office, an interim of five years must elapse before he can be elected a third time. The President possesses certain exclusive powers of a very important nature. He alone can appoint and remove at will not only cabinet ministers, clerks of department, and councillors of state, but also diplomatic ministers, consuls, and the higher provincial officers. He also inducts the higher legal and judicial functionaries; but the nomination of these officers, as well as of the ecclesiastical dignitaries, must proceed from the Council of State. The President has the power of distributing the army and navy according to his pleasure; and when, with the sanction of the Senate, he assumes the command of the national troops in person, he alone is vested

Chile.

with the right of bestowing naval and military commissions. In other circumstances, the appointments of this nature which he makes must be approved by the Senate. In periods of tumult and insurrection he can declare the towns and provinces of the republic in a state of siege.

The President is liable to impeachment for mal-administration for a year after the expiry of his authority. During that time he is not allowed on any account to leave the country, except with the permission of Congress. All the other officers of government are subject to the same law; but in their case the time is more limited.

Council of State.

Nearly co-ordinate with the President in the executive department is the Council of State. This body is composed of ministers in the exercise of their functions, of two members of the courts of justice, of an ecclesiastical dignitary, a general, an admiral, a chief of the administration of finances, two ex-ministers or diplomatic agents, and two former provincial intendants, governors of departments, or municipal magistrates, who must all possess the qualifications necessary for the rank of senator. The duties of the Council of State are, to advise the president in the administration of the government, and to act as a check upon him in proceedings which it may consider as injurious to the interests of the country. It proposes the removal of such officers of government as have been guilty of negligence in the discharge of their duties; and settles all disputes with regard to government contracts. It decides all doubtful questions that may arise between the several administrative departments of the government, or between these and the judicial tribunals. The President is also obliged to submit the annual fiscal estimates, and all laws contemplated or enacted by Congress, to the deliberations of this body. Should the advice they give in any particular case be adverse to the laws, they are liable to impeachment by the Chamber of Deputies.

Cabinet ministers.

The administrative department of government is conducted by four cabinet ministers. One presides over home and foreign affairs; another over justice, worship, and public education; a third is a minister of war and marine; and the fourth of finance. The President has no power of enforcing obedience to orders relating to any one of these departments until they have been confirmed by the appropriate minister. The ministers are individually responsible to Congress for the due discharge of all the duties pertaining to their respective branches of the administration, and also for whatever is done by them in common as a cabinet. They are entitled to be present and to take part in all the debates of Congress; but, unless holding at the same time the office of senator or of deputy, they are not allowed to vote in that body. Any of them may be impeached by the Chamber of Deputies for treason against the laws of the state, or for the mal-administration of the duties of his office. An action may be brought against them even by private individuals who have suffered by any of their acts, if the Senate, to whom appeal must in the first place be made, decide that there is sufficient ground for complaint.

Justice.

The tribunals of justice may be divided into three classes. Of these only two are properly judicial in their functions, the third being mainly political. The third class includes five tribunals, of which the Congress collectively and in its separate branches forms three with parliamentary jurisdiction, and the Council of State one with administrative powers. The fifth is the mixed tribunal, which was formed under the treaty with Great Britain in 1839, guaranteeing the mutual right of search in vessels suspected of slave traffic. It consists of a judge, an arbiter named by each party to the treaty, and a notary. In all cases relating to the validity of a capture there is no appeal from its decisions.

The first of the other two classes whose functions are more strictly judicial, comprehends the supreme courts and the three courts of appeal. The supreme court has direct supervision over all the others. The courts of appeal are composed of a certain number of legal ministers or justices, with a corps of special ministers to them in certain cases. These special justices, who form a remarkable feature in the Chilean system of legal administration, are taken from the intelligent classes connected with the military, the agricultural, the mining, and commercial interests of the country. In cases on trial pertaining to their respective interests they sit on the bench, and have an equal voice with the legal judges, both as to the law and the fact. These courts, to which disputed points from all other parts of the country are brought for adjudication, are established in Santiago, Serena, and Concepcion.

The same class comprehends four other tribunals, presided over by judges who, having been advocates, are termed, in contradistinction to the others, *learned* judges. Of these courts, one possesses the right of decision in all cases involving sums of more than L.30, or in which certain government officers are the parties. Its jurisdiction extends also to criminal cases. Another decides, in connection with the provincial intendant, fiscal causes; and its decision cannot be appealed from in any suits under L.40. The third of these courts, which is composed of one learned and of one commercial judge, together with the collector of customs, has the power of giving a final decision in revenue cases involving confiscation. The fourth has jurisdiction in suits for libel. But before there can be any prosecution in such cases, they require to be heard before four judges of the fact, whose duty it is to decide whether there be just cause for carrying them before the seven judges, who finally decide the case. At the second hearing the legal judge presides and decrees the penalty.

There are eleven kinds of inferior tribunals, some having as important spheres of jurisdiction as the lower grades of the superior courts; but differing widely in the nature and extent of their powers. They resemble each other, and differ from the superior courts in this—that the presiding judges are not educated lawyers.

The ecclesiastical and military tribunals, composed respectively of dignitaries of the church and officers of the army, decide in all cases pertaining to their several spheres of duty. The Exchequer Court, over which the chief of that department presides, takes cognizance of suits arising in matters connected with that branch of the administration. The tribunals of commerce consist of members appointed by all the commercial districts except Valparaiso, and exercise jurisdiction in all cases relating to mercantile affairs. The remaining tribunals, composed of the various grades of provincial officers, have under their jurisdiction a great variety of subjects relating to mining, public roads, theatres, some domestic matters, money claims, and the lesser crimes. The Domestic Court consists of five fathers of families, summoned by the political chief of the province or department in which they reside. It hears and decides upon the complaints of minors against their parents, for refusing assent to their marriage. Complaints of this nature are of more importance in Chile than in other countries, as majority is not reached by single men till the age of twenty-five, while it is attainable through marriage at twenty-one.

Provincial administration.

For the administration of its internal affairs, Chile is divided into thirteen provinces, each with subordinate departments, sub-delegations, districts, and two settlements. The names of the provinces are,—Atacama, Coquimbo, Valparaiso, Aconcagua, Santiago, Colchagua, Talca, Maule, Nuble, Concepcion, Arauco, Valdivia, and Chiloë, and of the settlements Magallanes and Llanquihue. Each of these provinces is governed by an intendant, who is nominated by the president, and holds office for three years. The departments are under the control of governors, who hold office for a similar term.

Chile.

The intendant generally acts as governor in that department in which the capital of the province is situate, and is, at the same time, mayor of the municipal corporation; but the authority of this body is very limited, as it cannot dispose even of its local funds without the permission of government. The sub-delegations are directed by subdelegadoes, who are appointed by the governors for a period of two years. Their jurisdiction extends only to minor criminal cases, and to civil suits involving sums of between L.8 and L.30; but they have also appellate powers from the decision of the inspector's court in actions for sums under L.2, 8s. The districts are presided over by inspectors, who are chosen by the people, and hold an office similar to that of justice of the peace. They manage also the local postage arrangements. Their decision is final in all suits for sums under L.2, 8s., but they also dispose of cases involving sums as high as L.8, with an appeal, however, to the sub-delegado. The offices of sub-delegado and inspector are compulsory; and those who decline to undertake their duties are liable to fines equal to the sums limiting their respective legal jurisdictions.

Church.

The Roman Catholic religion is the only form of worship recognised by the constitution of Chile; and the profession of any other is strictly prohibited by law. For the purposes of ecclesiastical administration, the country is divided into 4 dioceses (comprehending the archbishopric of Santiago and 3 suffragan bishoprics), and 157 parishes. A home mission, consisting of 2 prefects and of 7 missionaries, is also supported by government at the annual expense of L.4000. Each missionary receives a salary of L.62, 12s. per annum, for which he is expected to say mass daily, and teach reading and writing in the schools. Great efforts have been made to induce the Indians to adopt the religion sanctioned by the state. In the island of Chiloe, which is chiefly inhabited by native tribes, a propaganda has been established for this purpose; and 9 missionaries have been sent to spread the faith among the Araucanian Indians. These attempts have as yet been crowned with little success. Schools have been established for the young; but notwithstanding the liberal donations of clothing and other articles on the part of the priests, the attendance is said to be very small.

In return for her exclusive privileges, the church in Chile yields a large revenue to the public finances. In 1853 the tithes yielded the sum of L.105,388, while all the expenses for public worship amounted only to L.53,385, 4s. In 1854 they amounted to L.120,895; and in 1855, when they were commuted into a property tax, L.151,554. The expenditure in this last year amounted to L.48,417, of which L.23,539 were for building and repairing churches.

Although no form of dissent is professedly allowed to exist in Chile, a tacit toleration has for some years been accorded to an English Episcopal and also to an American Presbyterian chapel at Valparaiso, where the American and English residents constitute a considerable population. Although the attendance at these chapels indicates a religious indifference on the part of the Protestants, the government stands too much in awe of the priesthood to allow them full toleration; as any important concession to the professors of the Reformed faith might lead to a revolution. The power of the Roman Catholic priesthood is particularly manifested in the obstacles by which they endeavour to prevent the marriage of a Protestant and a Catholic. If a Protestant proposes to marry a Roman Catholic Chilena, he must either publicly apostatize from his own faith, or purchase a *dispensa*, by making a liberal present to the bishop of his diocese; and in all such marriages it is made an indispensable condition that the children be educated in the Roman Catholic faith. The same bigotry prevails in the laws which regulate the interment of Protestants, though the stringency of these has of late been somewhat relaxed In Santiago, adjoining the public cemetery, government has allotted a piece of ground as a burying-place for Protestants; and in Valparaiso and Coquimbo the same has been done by private individuals, with the permission of government; while in the churchyard of Talcahuano several Protestants are sleeping peacefully beside their Roman Catholic brethren.

Education.

Much attention is now given in Chile to the important subject of education, and this is in no small degree owing to the exertions of the late president, M. Montt. The first in rank of the educational establishments is the National Institute, composed of two departments—the university, and preparatory section—occupying one large edifice. The university has 15 professors, whose salaries range from L.200 to L.400 a-year; while the average number of students is about 220. No fees are charged, and any one who has the requisite elementary knowledge may attend the classes. It is governed by five deacons, a secretary, and representatives from the faculties of science, philosophy, humanity, medicine, law, political economy, and theology; who are also charged with the superintendence of education in the provinces. The preparatory section corresponds to our grammar or high schools; and here, too, education is free. Those who reside in the school pay L.30 a-year for board. In 1856 the number of scholars was 663, of whom 217 were boarders. The educational staff comprehends a rector, vice-rector, and 26 masters, whose salaries range from L.400 to L.40 a-year. There are also eleven inspectors, whose emoluments vary from L.40 to L.80.

The National Institute costs government about L.9000 a-year. In Santiago government also supports a military academy (annual charge about L.6000), a school for the instruction of mechanics (L.5200), a training school for teachers (L.2500), and a seminary for the education of priests (L.1200). In addition to these, an agricultural school, an academy of painting, an academy of music, a school for the deaf and dumb, and other useful institutions, are all supported at the national expense. A lyceum, on the same plan as the National Institute, is established in every provincial capital, and is supported by local taxation, government grants, and fees from pupils. In these institutions boarders pay an annual sum of L.20, and day scholars L 2, 8s.; but many receive instruction gratuitously. The directly practical branches of education receive the largest share of attention, but the learned languages are not neglected. The lycea of Talca, Concepcion, and Serena possess the privilege of granting degrees in mathematics and chemistry.

Besides these, government supports throughout the country 352 schools, where poor children are taught reading, writing, arithmetic, and the Roman Catholic catechism; the municipal corporations support 96 similar schools; and 315 schools are carried on by private individuals. According to a curious paper published by the minister of public instruction in 1856, there were 3794 children learning Spanish grammar, 1652 learning French, 1392 English, 1315 Latin, 325 German, 1 Greek, 1340 drawing, and 1774 music.

To aid in the diffusion of knowledge, government prints and disseminates all over the country cheap editions of standard authors, chiefly French.

The capital contains also an excellent observatory, a museum, and a public library with about 32,000 volumes.

Government pays for the education of 12,600 boys, and 3430 girls; the municipalities for 3680 boys, and 1470 girls; and those educated at their own expense in private schools amount to 6700 boys, and 3100 girls. The total expenditure of government for educational purposes in 1855 was L.55,560. The salaries drawn by professors and teachers during the same period may be estimated at L.21,000, of which government contributed L.9000, the municipalities L.7000, and the private schools L.5000. The average salary of a schoolmaster in Chile is L.3 per month, the highest L.20 per month. Akin to these statistics it may be added, that government contributes to 12 hospitals annually L.8000; and supports a madhouse (at L.500 per annum), a penitentiary (at L.5000), house of correction (L.1000), a convict establishment in the island of Juan Fernandez (L.1000), besides prisons, a company of French Sisters of Charity, dispensaries, and vaccination establishments.

Literature.

The press of Chile is in an improving and progressive condition. Eight or ten newspapers and one magazine, the *Revista Catolica*, are published in the republic. Of these, the first place is due to the *Mercurio*, both on account of primogeniture and fearless devotedness to justice. The mistakes committed by government and its officials, and the sallies of illiberality and ignorance of the clergy, as shown in their mouthpiece, the *Revista*, are censured in its columns with firmness and dignity; while it is the first to present a tribute of approval to whatever either of these do worthy of praise. The *Ferrocarril*, another daily paper, is fast increasing in popularity; it is cheap, abounds in "town-talk," and presents its

Chile.

readers with some very well written articles. Government makes known its decrees and enactments through its gazette, the *Araucano*. The only other paper of note is the *Diario*, published, like the *Mercurio*, in Valparaiso. The literature of Chile is supported by several able writers.

Army and navy.

The army of Chile averages about 2700 men, the militia 40,750, and the invalids 530. The whole of the troops are under the superintendence of general inspectors. Of superior officers there are,—1 lieutenant-general, 5 generals of division, 3 brigadier-generals, 20 colonels, 51 lieutenant-colonels, and 126 captains. But several of these officers are either on the retired list, or engaged in other departments of military service. One brigadier-general superintends the military academy (founded in 1842), in which about 40 cadets receive instruction.

The fleet of Chile, which acquired so much distinction for its exploits under Lord Cochrane, and was then manned chiefly by British or North American seamen, is now composed of the old frigate *Chile* (at present used as a store-ship), 2 brigs, 1 brigantine, 1 barque, and 2 steamers. A naval school was established at Valparaiso in 1845.

The total expenditure of the war department in 1855, or, in other words, the cost of the army, navy, national guard, and pension fund for maimed soldiers and sailors, and their widows and orphans, was L.312,216, 14s. The annual pay of a private in the Chilean service is L.19, 4s., of a lieutenant, L.96; of a captain, L.144; of a lieutenant-colonel, L.336; and of a colonel, L 542. The general-in-chief has a yearly salary of L.1300; generals of division, L.700; and brigadier-generals, L.542.

The pay of a vice-admiral is L 1300 a-year; of the captain of a first-rate ship, L.768; of the captain of a corvette, from L.110 to L.180; and of a midshipman from L.84 to L.110.

Population.

Cities.

The cities and towns of Chile, with the exception of Valparaiso, are built generally upon the same plan. Their most striking peculiarity is, that they are divided into squares of equal size, the sides of which are about 137 English yards in length, and inclose an area of about four acres. Within each of these quadras there are parallel rows of broad and well-paved streets, intersecting each other at right angles. The houses are also built in the form of a square, inclosing one or more courts, into which the various apartments look; and are of timber, bricks, and adobes, which are large bricks formed of mud mixed with chopped straw, and dried in the sun. The unoccupied spaces are in most cases laid out in gardens, and stocked with fruit trees and flowers. In the larger cities great taste and elegance are displayed in the furniture of the houses of the wealthy, the greater part of which is supplied by the principal upholsterers of Paris. Every drawing-room contains its piano from the first London or Paris makers: and as the Chilenas are passionately fond of dancing, a pile of fashionable waltzes, quadrilles, and polkas, is generally seen beside it.

Public buildings.

The most splendid public edifice in Chile is the mint, which is built of brick, at a cost of L.165,000, and contains the apartments of the president of the republic. In ecclesiastical architecture Chile is inferior to most Roman Catholic countries. The majority of the churches are very plain; and the internal decorations, paintings, and images are for the most part of a very paltry description. The Compañia and Santo Domingo, however, display considerable taste. The cathedral church has been designed on a very grand scale; and although still unfinished, has already cost L.340,000. The cathedral of Serena is small, but much admired for the style of its architecture,

which, with the light magnesian limestone used in its erection, is well calculated to resist the dangers arising from the frequency of earthquakes.

In costume the wealthier classes in Chile have discarded the picturesque dress of their Spanish ancestors, and cannot now be distinguished from those of London and Paris.

In complexion the natives present considerable variety. Among the peasantry the Araucanian copper colour still prevails; but in consequence of the large infusion of European blood, a greater variety of shade is to be found in the upper and middle classes. In general their complexion closely resembles that of the natives of Southern France.

Amusements. The amusements of the upper classes are also borrowed from the habits of European society. In the ball-room the dances are those of the Old World, with the exception of the *zambaqueca*, a dance peculiar to the republics of South America, and only danced in Chile at the breaking up of parties when all have become very familiar. In fashionable assemblies the piano is the accompaniment; but amongst the poorer classes its place is taken by the guitar.

Theatrical amusements are well patronized in Chile It contains five theatres, of which the best is in the capital, built at the expense of L.70,000, and capable of containing 2000 people; next in rank is the theatre of Valparaiso, a very commodious edifice; and then those of Copiapo, Coquimbo, and Concepcion. Spanish and French plays, and the Italian opera, are well received in all these, although it must be confessed that much still remains to be done to bring them up to the standard of European excellence. Races and military reviews are common in Chile. The former of these are held on courses about six hundred yards in length; and as the issue of the race depends on a successful start, considerable ingenuity and tact are shown in training the horses to commence with a sudden bound.

Mineral productions. Chile is rich in almost every class of metals; and of late years the silver mines have yielded enormous quantities of ore. The metals at present discovered are gold, silver, copper, lead, antimony, cobalt, zinc, nickel, bismuth, iron, molybdenum, and quicksilver; but the only ores which are worked are gold, silver, copper, and occasionally quicksilver. The latter has now been abandoned in consequence of the low price of mercury, caused by the quantity produced in California. The metals are found in all the series of rocks between granite and trachyte, in veins generally running from N. and N.W. to S. and S.E.; in some places, however, their course is irregular; or they extend E. and W. The auriferous veins run nearly parallel to the grain or imperfect cleavage of the surrounding granite rocks. Gold is found most abundantly in the beds of detritus derived from the degradation of the upper portion of the rocks. Copper ores, containing a small quantity of gold, are generally associated with micaceous specular iron. In the hills of Altruc, about 4 leagues from Rancagua, in the province of Santiago, are the only gold mines worked with any spirit, excepting some new mines near Copiapo, and they are remarkable for the variety of minerals mixed with the gold, such as galena, blende, copper and iron pyrites, and peroxide of iron. These substances are found disseminated in quartz veins running nearly N. and S. Near Illapel are some very poor gold mines, in the beds of the gypseous formation, in altered felspathic clay-slate, which alternate with purple porphyritic conglomerate.

Silver. Until 1832 the only silver mines in Chile were those of Dehesa, San Francisco, San Lorenzo, Sema and San Pedro Nolazco in the province of Santiago, and Arqueros mineral district, about 17 leagues from Coquimbo; but these mines now produce very little silver, and are nearly abandoned for the rich silver mines in the province of Atacama, near to Copiapo. Within a circuit of 25 leagues from Copiapo there are 19 silver mineral districts; the richest are Chañarcillo and Tres Puntas. In Chañarcillo the upper part of the mines produce native silver, iodide, and bromide, associated with chloride of silver, and carbonate of lead. In the "Colorado" mine of Chañarcillo, embolite with native silver is occasionally found. In the mine of San Antonio, in the same district, is found bismuthic silver ore combined with native silver, copper, and arsenic. As the mines become deeper, the silver ores are changing principally into what the natives call "metales frios" (cold ores); these contain different proportions of antimony, sulphur, and one sort a little arsenic. The dark red silver ore is a pyrargyrite, containing sulphuret of silver and antimony, with sometimes a little arsenic. The gray ore contains silver, arsenic, and antimony. Some of the mines in Chañarcillo yield nearly pure silver; the most productive are in the hands of four or five large capitalists. The ground near some of the richest mines is sometimes sold at enormous prices, the price being in some regulated by the probability of rich veins of metal running into it. In Copiapo a regular traffic is carried on in buying and selling "barras" (a twenty-fourth part) in different mines.

A railroad runs from Caldera to Copiapo, a distance of 54 miles, and from that city on to Chañarcillo, a distance of about 50 miles; and a tram-road to the rich mineral district of Tres Puntas (8400 feet above the sea) has recently been completed, by which the miners are now enabled to send down the poorer silver ores which they formerly threw away.

Copper. The mines of copper may be said to occupy the first rank in the productions of Chile. The exports of copper ingots and ores in 1852, according to their market value at the time of shipping them, were equal to nearly L.800,000; in 1854 they amounted to L.864,520; and in 1855 to L.1,211,130. Copper is found in more or less abundance from the province of Santiago to the most northern confines of Chile. It is generally discovered in the lower granitic and metamorphic schistose series. The copper ores found in Chile consist of sulphurets, copper pyrites, oxysulphurets, found in Andacollo, with thin laminæ of native copper, arsenical copper (sometimes called domeykite), found in the Calabazo mine near Coquimbo and in that of San Antonio, near Copiapo, gray copper, red oxide, malachite, azurite, hydrosilicate, or chrysocolla, olivenite, protoxide, and deutoxide. Vanadiate of copper has lately been found in cavities in an arseniophosphate of lead, along with amorphous carbonate of lead and copper, in Mina Grande or La Marquesa, near Arqueros. That rare ore, the muriate of copper, or atacamite, occurs at Remolinos and Santa Rosa in veins in granite. The principal mining districts are Aconcagua, Illapel, and Tamaya, about 40 miles from the coast, and 70 from Coquimbo. This last district is a mountain about 3500 feet above the sea, which produces about 150,000 quintals a-year of various kinds of sulphurets, of a produce from 9 to 64 per cent. Tambillos, 10 leagues from Coquimbo, produces principally poor sulphurets; Runeral, near the river, entirely poor carbonates; Andacollo, carbonates, oxides, oxysulphurets, and native copper; La Higuera, black sulphurets and pyrites; Herradura de Carisal and Huasco, carbonates and sulphurets of low produce. In the Cordilleras above Huasco are some mines containing ores of copper, silver, and lead combined together; but the silver does not exceed 70 marks the cajon of 64 quintals Spanish.

Cobalt. Cobalt is found in the province of Santiago, near the Cordillera called Caro del Volcan; it is an arseniate containing from 18 to 20 per cent. of cobalt. At Tambillos is found glance cobalt, and arsenite or erythrine; the former sort is frequently combined with nickel. The mines have been worked some years, and the ores shipped to England. In Huasco similar ores are found, but the mines have lately been abandoned.

Nickel. Nickel has been found in considerable quantities in a mine in the Cordilleras above Copiapo.

Zinc, &c. The sulphuret of zinc is found in various parts; likewise antimony, lead, manganese, bismuth, mercury, and molybdena; iron ores of every description are very abundant; amongst the latter is coquimbite, or white copperas, and copiapite, or yellow copperas. It is much used by the natives for dyeing, tanning, and in the manufacture of ink.

Gypsum. Gypsum is found in immense beds, particularly in the valley of the Pinquenes, and other places in the province of Santiago. The fine massive variety called alabaster is found at the Salto de Agua, near to Santiago, of a quality nearly equal to that of Italy.

Lapis Lazuli. Lapis Lazuli has been found in the Cordilleras above the province of Coquimbo, but it is impossible to convey large slabs to the coast, and the principal use of the small pieces is to make ultramarine; and as the artificial equals the native in brilliancy of colour and permanency, it is not likely to be of much value.

Coal. In the province of Concepcion, the coal mines are becoming of great importance. At present they are confined to two districts, Coronel and Lota; the former has 12 mines in full work, but the latter not so many. The Concepcion coal is excellent for the manufacture of gas and for domestic purposes;

but for the smelting of copper ores it requires to be mixed with English coal. Its average price at the pit-mouth may be quoted at L.1 per ton; and the average annual produce, when the gasworks of Santiago, Valparaiso, and Copiapo are in full operation, may be expected to amount to 400,000 or 500,000 tons.

Vegetable productions.

The annual value of the agricultural produce is estimated by the government at L.1,481,776; but as rural produce to the amount of L.1,090,000 is exported, we may take it for granted that at least twice the amount exported is consumed in the country, and therefore the more correct estimate will be L.2,180,000. Irrigation is extensively practised, without which the greater part of Chile would be unproductive. The level lands thus watered yield abundantly corn and wine, and rich pasture on which the farmers fatten the cattle bred upon the hilly portions of their estates. These hills are sparingly covered with a peculiar kind of short and wiry grass, which, after one winter of abundant rain, lasts for two seasons, even although the succeeding winter may have been dry.

These arid regions likewise produce the carbon tree, which affords excellent firewood, but is used for nothing else. The carrob tree, which, in defiance of a broiling sun, stretches out his spacious limbs covered with foliage, forming a most delicious retreat to the weary traveller by day as well as by night; the espino (*Acacia cavanea*), inferior to the carrob tree in size, hardness, and durability of its timber; and the great torch thistle, whose long, smooth spines are used by the country people for knitting-needles, and whose interior woody substance, stripped of its fleshy bark, forms the beams and rafters of their cottages. Timber is abundant in all the provinces S. of Santiago, but chiefly in Arauco, Valdivia, and Chiloé, which may be termed the forest region of Chile. There are altogether above a hundred different kinds of indigenous trees, of which not more than thirteen ever shed their leaves. Several have been found serviceable in ship-building; but for purposes of house-carpentry, none afford an adequate substitute for pine. Ornamental woods are scarce, and too soft for the use of the cabinetmaker. The principal timber trees are the Chilean oak, which attains a height of 40 feet; the lingue (*Persea lingue*), 90 feet; the cypress (*Libocedrum chilense*); the patagua (*Tricuspidaria dependens*), 40 feet; the laurel (*Laurentia aromatica*), 60 feet; the luma (*Myrtus luma*), 30 feet; the Araucanian pine, 150 feet; and the alerce, or Chilean cedar (*Libocedrus tetragonia*). The most valuable is the Chilean cedar, a soft but durable wood, and not liable to warp. The trunk is divided into pieces of 8 feet long, and so straight are its fibres that they are split into small boards 6 or 7 inches broad, and about half an inch thick—a single trunk yielding 500 or 600. In Valdivia and Chiloe they form the chief article of export, and are used for purposes of exchange. The roble grows to the height of the English oak, and retaining its soundness in water, furnishes excellent stakes. The bark, when prepared with lime, is used for tanning, and imparts to leather a reddish colour. The timber of the luma bears a closer resemblance to the English oak than that of the roble. The laurel is a tall handsome tree, but its wood is hard, and warps so much that it is only suitable for the coarsest work. The cypress grows to a height exceeding that of the loftiest trees in England. Its wood is of a red colour, and is used for beams, doors, pillars, and ornamental flooring. In the S. of Chile, the quillay tree (*Quillaja saponania*) flourishes in great abundance. A decoction of the bark is of great service in clearing the colours used in dyeing, in cleansing articles of silk and woollen cloth, and as a wash for the hair.

The Araucanian pine flourishes on the high lands S. of the Biobio, and grows in pairs—the female under the foliage of the male. The fruit, which takes two years to ripen, is arranged conically, each cone containing from 50 to 100 nuts, 2 inches long, and which, when cooked, form more delicate eating than chestnuts. Under the governorship of O'Higgins their trunks were used for ship-masts; but at present the expense of bringing them to the coast prevents their being employed as such. In the gardens of Coquimbo, a fruit tree known by the name of the *Lucumo achraes* is much cultivated. Its fruit, which is about the size of a small orange, resembles somewhat a hard-boiled egg, but is too dry and insipid to form a palatable article of food.

The potato, whose introduction into Europe formed an important era in the history of agriculture, is indigenous to Chile, or, as some assert, to Peru. In the equatorial regions of South America this plant was formerly cultivated on the sides of the Cordilleras at an elevation of many thousand feet above the limits of perpetual snow in the latitudes of Europe. It is still extensively cultivated in Chile. Much attention is also bestowed on the production of the French bean. This vegetable is a standard dish with all classes, and is to the Chilean what oatmeal is to the Scotchman.

The supply of the various kinds of fruit is very abundant in Chile. Apples, pears, cherries, strawberries, peaches, figs, oranges, melons, olives, quinces, and pumpkins abound, which, however, compared with those of England, are rather inferior. Yet, where cultivated with care, as in some private gardens in the neighbourhood of Santiago and Valparaiso, they are unrivalled in quality.

Animals.

In Chile the most formidable animal is the puma. On account of its ravages in the farm-yard, it is frequently hunted with dogs, or caught by the lazo. The guanaco roams about among the lower regions of the Chilean Alps in herds numbering from 20 to 100. The vicuña has fixed his abode at a higher elevation. The huamul is not found in such numbers, and is unknown in the Andes beyond the bounds of Chile. Otters, wild cats, foxes, and chinchillas are numerous.

The horses of Chile are inferior in strength and height to those of England, but greatly superior in point of endurance. The mule is the beast of burden, and will carry on an average a load of 355 lb. a distance of 20 or even 30 miles per day. The breed of cattle is good; those of sheep and pigs are fast improving.

Among the birds of Chile the most remarkable is the condor, which is easily recognised by the white ruff encircling its neck. As its wings on an average extend 8 or 9 feet, its flight has a very majestic appearance. Humboldt mentions having seen one flying at the height of 22,000 feet above the level of the sea. They scent an exposed carcase from a great distance, and soon gather round it in immense numbers. The turkey-buzzard is also very common; and when these meet the condors over the same prey, the coveted prize becomes the subject of fierce contest. These two species are most abundant in the northern districts; while eagles, hawks, and owls are more numerous in the S. The only song-birds worthy of notice are, —the tenca, the thrush, the tordo (a kind of blackbird), and the moylloyca (a kind of redbreast); but none of these can rival the notes of our English birds. The tenca is said to emulate the mocking-bird in imitative power. The tapaculo (*Pteroptochus albicollis*), a bird about the same size as the thrush, rarely flies, but runs about with great agility, emitting an odd but cheerful note. The chingol, or sparrow, has gayer plumage than his European representative. Besides these, parroquets, flamingoes, partridges, and woodpeckers abound in several localities. The pelican, the albatross, the penguin, and the shag, of which there are numerous varieties, frequent the shores.

Great varieties of fish are found off the coast of Chile, and of these the pichihuen, which is caught chiefly in the Bay of Coquimbo, is regarded as a choice delicacy. There are abundance of small sweet oysters off the coast of Chiloé; quantities of huge mussels, barnacles, and fissurellæ, off Concepcion; and large clams off Coquimbo; besides sea-eggs, cockles, limpets, &c., which are found in great plenty all over the coast.

Of the reptiles of Chile, the lizards are the most numerous, and they are very harmless. Serpents are found varying from 12 to 30 inches in length. The honey-bee is propagating very fast. Of beetles, there are from 3000 to 4000 species not found in Europe.

Agriculture.

Agriculture as a science is scarcely known in Chile, and everything connected with the farm is still of the most primitive description. The plough is a clumsy one-handed instrument, formed from the crooked trunk of a tree. In using it the peasant grasps its handle in his right hand, while in his left he wields a long sharp-pointed stick to goad on the oxen, which are invariably yoked not by the shoulder but by the horns. The operation of treading out the corn is performed by mares. For this purpose the sheaves are piled up in bundles in the centre of an extensive circus, having an empty space of from 10 to 20 feet between the heap and the inclosure; and some of the bundles being spread over this space a troop of mares are made to gallop over them until all the

grain has been beaten out. Winnowing is performed by throwing up spadefuls of grain into the air on windy days. All the other operations of the farm are performed in an equally unskilful and tedious manner. So rude is the mode of harvesting wheat, barley, and beans, that at least from 6 to 7 per cent. of the produce is lost, and goes to breed swarms of vermin on the farm. The labourers earn from 1s. to 1s. 6d. a-day, with food.

Maize is largely cultivated in all parts of Chile, but not to such an extent as wheat. As the corn plant spreads out into numerous stems, half the quantity of seed used in England is quite sufficient to cover the field with an abundant crop.

The provinces of Aconcagua, Santiago, Talca, Nuble, Maule, and Concepcion, yield annually large crops of wheat, maize, and French beans.

The lands of Aconcagua produce about 50 or 60 fanegas of wheat on every quadra, equal to about 30 or 40 bushels an acre; Santiago from 30 to 35 fanegas on every quadra; Colchagua from 25 to 30; Maule from 15 to 18; Nuble, Talca, and Arauco from 15 to 20; and Concepcion from 8 to 10. The total produce of wheat may be estimated at 1,000,000 quarters, but is increasing annually. The price of wheat has risen considerably of late years. Between 1840 and 1850 the average price was from 18s. to 24s. per quarter; while in 1851 and 1852 the average price ranged from 42s. to 44s.; and in 1856 from 55s. to 65s.

The backward condition of agriculture in Chile is owing to the thinness and natural indolence of the population, and the absence of easy means of transportation. The government has for several years taken vigorous measures to encourage emigration from Europe into Chile, chiefly with the view of promoting the agricultural interests of the country. A great number of German agriculturists have already settled in the province of Valdivia, and every year is making additions to their number. Between 1848 and 1852 a single house in Hamburg sent out more than 1000 individuals. The presence of these industrious settlers cannot fail to exercise a favourable influence on the habits and pursuits of the native population.

Manufactures.

Manufactures are here as yet only in their infancy. In Santiago a cloth factory has been commenced under the protection of government, but hitherto it has produced only the coarser kinds of cloth, such as are used in the army. All the other looms in Chile are worked by the hand, and used in the production of carpets and ponchos, some of which, made of vicuña wool, are of a very fine texture. A large portion of the population wear home-made stuffs, especially woollen. The importation of British goods is, however, increasing; and the facility with which foreign stuffs can be imported has checked the establishment of important manufactures. Coarse earthenware, cordage, combs, leather, saddles, and wooden stirrups, are made in several parts of the country. In Valparaiso and Maule ship-building is carried on. In the cities and larger towns most of the mechanical trades which exist in other parts of the world are pursued.

Commerce.

The commerce of Chile has vastly increased since the time when the country lay torpid under the yoke of Spain. As soon as it had recovered from the unsettled condition caused by the revolution, business of all kinds acquired new energy, and the trade, freed from its oppressive restrictions, extended to the larger ports of the United States and Europe. A few years were sufficient to show a large increase in its export and import trade, and Valparaiso soon rose to be a flourishing port.

In 1855 Chile exported silver, copper, and cobalt, to the value of L.2,063,300; of this amount L.1,211,130 was in copper, L.850,530 in silver, and L.1640 in cobalt. Of wheat the average annual export may be estimated at 95,000 quarters, which, at 50s. the quarter, gives L.237,500; and the average value of the wool exports at L.50,000. The greater part of the jerked beef, ham, fat, butter, and cheese produced in the southern provinces is exported to those in the north, where it is consumed by the miners. Among the minor exports are,—horns, hoofs, rags, and timber.

In return for her various exports, Chile receives from England cotton goods; from France silks and various articles of luxury: and from other countries a variety of articles for domestic use. Chile has reciprocal treaties of commerce with Austria, Brazil, Belgium, Bremen, Sardinia, Denmark, France, Great Britain, Prussia, Sweden, Norway, Tuscany, Hamburg, Lubeck, Oldenburg, the United States, Peru, Ecuador, and the Sandwich Islands. Her commercial relations are most extensive with Great Britain and the British colonies, the imports into Chile amounting in 1852 to L.159,613, and the exports to L.1,093,772. Next in importance is the trade with France, the United States, and California. With the other republics of South America her commercial transactions, which were once considerable, appear to be on the decline.

Table showing the value of the Imports and Exports of Chile for 1855. This Table does not include the value of goods landed in bond and afterwards re-shipped, amounting, for that year, to L.1,566,858. Nationalized merchandise are those foreign goods on which custom dues have been paid:—

Countries.	Value of Foreign Goods Imported.			Total.	Value of Native Produce and Merchandise Exported.		Total.
	Free.	Belonging to Government Monopoly.	Paying Duty.		Native Produce.	Nationalized.

Chile.

TRANSIT TRADE.

Received.

	1854.	1855.
By Sea	L.4,412,649	L.5,197,785
Across the Andes	184,362	205,191
Total	L.4,597,011	5,402,976

Despatched.

By Sea	L 949,307	1,167,582
Across the Andes	142,680	224,516
Total	L.1,091,987	L.1,392,098

In 1854, 2526 vessels, having an aggregate burden of 752,347 tons, entered, and 2461 vessels, of 729,832 tons, sailed from Chile; and in 1855, 2757 vessels, of 841,842 tons, entered, and 2681 vessels, of 820,024 tons, sailed from Chile. Of those that entered during the latter year, 127,633 tons were English; 54,905 United States; 10,552 French; 7074 German; and 6366 Peruvian. Of those that sailed, 131,530 tons were English; 51,651 United States; 9001 French; 7557 Peruvian; and 7034 German.

The articles of importation that have been increasing most are sugar, tea, coffee, and iron; and as the rate of increase of these articles far exceeds that of the population, it serves to prove that the wealth of the nation is increasing.

The following may be considered as a pretty correct estimate of the value of the annual productions of Chile:—

Silver, copper, cobalt, and gold	L.2,100,000
Coal	300,000
Wheat	2,400,000
Minor products of the country	200,000
Total	L.5,000,000

Revenue.

The revenue of Chile is in a very prosperous condition, exhibiting a surplus of receipts over expenditure in the returns of several years. In 1845 the revenue amounted to L.1,083,169, 13s., leaving, after the necessary outlay, a surplus of L.410,215. In 1849 the revenue, including the surplus from 1848, was L.1,352,210. The surplus of 1849 was L.57,048, and this, together with the receipts of 1851, amounting to L.885,381, 8s., was entirely swallowed up during the revolution of the latter year. With the restoration of peace in 1852, the revenue rose to L.1,096,096, which, with the sum of L.24,000 paid by Peru as interest for its debt, gives an increase of L.234,714, 12s. over the income of the preceding year. In 1854 it amounted to L.1,189,244, and in 1855 to L.1,257,505.

Table of Revenue for 1855.

Customs	L.752,904	15	0
Government monopolies (sale of tobacco and cards)	181,665	15	0
Land-tax	151,754	4	0
Licenses	13,182	12	0
Stamp-paper	15,668	14	0
Mint	12,865	16	0
Post-office	15,464	14	0
Auction duties	1,185	12	0
Peaje	12,578	4	0
Catastro	19,987	0	0
Alcabala	55,570	12	0
Accidental sources[1]	24,677	6	0
Total	L.1,257,505	4	0

The catastro is a duty of 5 per cent. levied upon the sale of lands. The alcabala is a duty of 4 per cent. on the sale and exchange of immoveable property, and of 2 per cent. on the sale of mines. Peaje consists of tolls and pontages, and is levied on cattle, mules, vehicles, &c.

The customs levied at the different ports on foreign goods in 1851 were as follows:—

Valparaiso	L.515,659	1	9
Coquimbo	18,495	3	0
Huasco	5,616	3	3
Copiapo	30,917	9	6
Talcahuano	4,646	14	9
Constitucion	54	8	0
Valdivia	294	14	9
Ancud	830	17	6
Santa Rosa de los Andes	2,487	19	0
Total	L.579,002	11	6

Owing to the civil war of 1851, the ports of Coquimbo and Talcahuano remained closed against all commerce, both foreign and domestic, from the 7th September to the end of December in that year.

The exports of these two ports consequently fell off, as compared with the preceding year, L.59,474, 1s. 6d. in value; and the number of vessels which entered and sailed was only 517 in 1851.

The custom-house returns show a corresponding increase in the amount of duties received.

In 1850 they were	L 474,894	16	4
And in 1851 they were	579,002	11	6
Total	L 104,107	15	2

In 1851 several important restrictions were removed from the customs code of Chile, which had been only partially modified in 1834. The exportation of national produce was then declared free in principle, but a small duty was to be maintained for a short time upon a very few articles. All imports, with the exception of iron, steel, zinc, cotton, mercury, coal, agricultural tools, surgical instruments, and books, are liable to a moderate duty. Jewellery pays 2 per cent.; horses, mules, and dried fruit, 6 per cent.; shoes, linen stuffs, furniture, and various articles used only by the wealthy classes, 30 per cent. The duty on white wine is reduced to 10 reals per dozen, and on red to 8 reals. Teas pay 2 reals the pound. Grain of all kinds is subject to a moveable tariff. As long as the price in the home market does not exceed 16s. 8d. the fanega of 150 lb., foreign grain pays an import duty of 12 reals the fanega; but if the price rises to 20 shillings, the duty falls to 8 reals; and if it exceeds 25 shillings, the import duty ceases altogether.

Chile has lately imitated the postal arrangements of England, and letters are forwarded on a stamp, costing about 2½d., to all quarters of the republic. The number of letters which passed through the post-office of Santiago in 1852 was 71,168.

Government derives considerable profit from its monopoly of tobacco and playing-cards. To prevent the smuggling of tobacco, the authorities are obliged to maintain an expensive establishment of officers along the coast and among the mountains; and so stringent are the laws in regard to the growth of tobacco, that when it springs up, as it does, spontaneously in the court-yards of the houses, the inhabitants are liable to a fine if it be not immediately rooted up. But for these oppressive restrictions, tobacco would undoubtedly rank high among the exports of Chile, and add greatly to the revenue.

Expenditure.

The national expenditure for the year 1855 was thus distributed:—

The Ministry of the Exterior and Interior	L.259,436	2	0
The Ministry of Justice, Public Worship, and Education	184,804	12	0
The Ministry of the Hacienda (Chancellor of the Exchequer)	340,480	2	0
The Ministry of War	312,216	14	0
Total	L.1,096,937	10	0

The first sum includes the salary (L.2400) of the president of the republic, the salaries of the intendants and legations, the sums annually paid to the Indians, the grants to the hospitals, and the money expended in promoting colonization. The second sum includes the salaries of the minister (L.1200), and of the president (L.900) of the supreme court; and the third the salaries of the *employés* of the exchequer, the treasury, the mint, the customs, and the interest of the national debt, which last amounts to L.1,732,595.

Weights and measures.

The weights and measures of Chile are the same as those used in Spain, but according to the decree of January 1848, those of France are to be substituted in January 1858. The largest dry measure of capacity is the fanega, which is subdivided into twelve *almuds*, and contains 5,430,626 cubic inches. The usual corn measure is the half fanega, which is a long parallelopipedon having one of its narrow sides trapezoidal. The imperial bushel contains 2,218,274 cubic inches, so that the fanega of Chile is to the former as 2·448 to 1. The average weight of a fanega of wheat is 157 lb.

The old table of long measure is divided into lineas, pulga-

[1] The accidental sources are rents and sales of government property, fines, interests, discounts, and recovery of bad debts.

Chile.

das, pies, varas, and cuadras, or lines, inches, feet, yards, and quadras. Corresponding exactly in value to troy weight there are the Spanish granos, onzas, and libras,—or grains, ounces, and pounds; and to avoirdupois weight, onzas, libras, and quintales, or cwt. In liquid measure the English quart is equal to 1·022 Spanish cuartillo, and the imperial gallon to 4·089 cuartillos. Gold is bought by the castellano or marco. Its relative fineness is expressed by quillates or carats, 4 granos or grains making one quillate. The weight of the marco is equal to 4800 Spanish grains, or to 7 oz. 7 dwt. and 22 gr. English troy weight. The standard fineness of gold is 21 quillates. The relative fineness of silver is expressed by dineros, the dinero being equal to 24 granos; and the standard fineness of that metal is 10 dineros and 20 granos. The gold and silver coins contain nine-tenths of pure metal, and one-tenth of alloy. The copper coins are quite pure, containing no alloy. Their names, value, and weight may be most conveniently represented by means of the following table:—

					Spanish Granos.		French Grammes.
Gold—Condor.....	=	L.2	0	0	305·540	or	15·253

The bushel is equal to 2⅔ almudes, and the quarter (8 bushels) to 21⅓ almudes.

The communication between the several towns of Chile is now greatly facilitated by roads, railways, and steam-vessels. The excellent road from Santiago to Valparaiso was constructed at a great cost by General O'Higgins, when president of the republic. A road, generally kept in good repair, connects the towns of Atacama and Concepcion. A railroad has been already established between Copiapo and Caldera; and in 1852 the president M. Montt laid the first stone on the line (about 90 miles in length) between Santiago and Valparaiso, and it is now rapidly advancing to completion. Another has been commenced between Santiago and Talca; while proposals for others from Serena to the sea, from Copiapo to Tres Puntas, and from Concepcion to Talcahuano, have also been laid before Congress. A line of electric telegraph has also been established between Valparaiso and Santiago.

Chile.

In 1835 the exclusive right of steam navigation between the ports of the republic was granted to a company, which commenced its operations in 1840. A similar privilege was afterwards extended to the same company by the governments of Peru, Ecuador, and New Granada. The communication between England and Chile is maintained by the way of the Isthmus of Panama. Steamers sail between England and Chagres, from which, by travelling across the isthmus, the Pacific is gained in two or three days, and the remainder of the journey continued in steam-vessels. The voyage from England to Chile by this route occupies about thirty or forty days.

History.

The name Chile is supposed to be derived from "Tchili," a word belonging to the ancient language of Peru, signifying "snow." The country first became known to Europeans in the sixteenth century. It was then to a considerable extent under the dominion of the Incas; but had been previously inhabited by certain tribes of Indians of a warlike and ferocious race, who at the period of the Spanish invasion still maintained their independence in a great portion of the country.

In the time of the Inca Yupanqui, grandfather of the monarch who occupied the throne of Peru on the arrival of the Spaniards, and the tenth in succession from Manco Capac, the reputed founder of the Peruvian empire, the first attempt was made by the Incas to extend their dominion over the territory of Chile. Yupanqui, leading his army across the desert of Atacama, and penetrating into the southern regions of the country, made himself master of a considerable portion of it. The permanent boundary of the dominions of this prince is said by some writers to have been determined by the River Maule; while others are inclined to think that the Rapel constituted the extreme limits of the Peruvian empire towards the south. The latter opinion is to some extent supported by the fact, that the remains of an ancient Peruvian fortress, apparently marking the frontier, are still found upon the banks of the Rapel; while no such remains are known to exist in any part of the country situate farther to the south. It is also worthy of remark, that this place of defence has evidently been built in the same manner as the frontier forts of Callo and Asuay, which were in all probability intended to answer a similar purpose in the province of Quito.

All the endeavours that were afterwards made by the Inca to extend his dominions further southward were unsuccessful. The better portion of the country still remained in possession of its native defenders till the arrival of the Spaniards in the year 1535, under the command of Almagro, once the friend and companion of Pizarro. For two years, amid almost unparalleled hardships, this general endeavoured to make head against the natives, who obstinately defended their soil; but at the end of that period he was obliged to retrace his steps over the Andes into Peru. Undaunted by the failure of Almagro, Pizarro resolved to attempt the conquest of Chile. He accordingly sent forward on this expedition 150 Spanish troops, with a body of Peruvian auxiliaries, under the command of Don Pedro de Valdivia, and was preparing to follow in person with a larger force, when he was assassinated in 1541.

Meanwhile Valdivia entered Chile, overran a great part of it, and fighting his way onwards, encamped at length on the banks of the Mapocho, where he founded the city of Santiago, the present capital of the republic. For the period of twelve years he maintained his position in the country. By the end of that time he had penetrated into the southern division of Chile, where, in addition to several other cities, he founded that which is now known by his

name. His life and conquests were at last brought to an end in a desperate engagement with the Araucanian Indians.

After these events, the war continued to be carried on with various success for the long period of 180 years. At the end of that time, however, the Indians had succeeded in altogether recovering their original possessions, and all the cities founded by Valdivia fell into their hands. For another century, however, they were exposed to the constant inroads of the Spaniards, who were unwilling to give up all hope of ultimately conquering the southern part of Chile. At length, in the year 1722, this sanguinary war was brought to a termination by a treaty which defined the River Biobio as the boundary between the Indian and the Spanish territories.

That part of the country which remained in possession of the Indians lay chiefly between the River Biobio and the island of Chiloë. All the territory N. of this river was entirely subject to the dominion of the Spaniards. It was divided by them into thirteen districts or provinces. Most of these provinces were very irregular in size, some of them extending from the Andes to the sea, while others, whose locality was nearer to the mountains, or upon the sea-coast, occupied only about half of that space. In the political contest between Spain and her American colonies, the inhabitants of Chile declared their independence, which, after a contest of some years, was acknowledged by the parent state.

A long period of profound peace followed the treaty which had been concluded with the Araucanians in 1722. During that time, however, changes of great importance were gradually developing. A new and important class of inhabitants had arisen in the country, composed of the Creoles or natives of Chile, who were of Spanish extraction, and who spoke the Spanish language. By a perverse course of misgovernment, the authorities in Spain completely alienated the minds of this class from the mother country. It was unfortunately a maxim with the home government, that the colonies existed only for the sake of Spain. The viceroys, captains-general, and officials of all grades, instead of conciliating the Chilenos, regarded them only as a means of furthering their own aggrandizement. Their insolence and tyranny, persisted in for many years, at length excited against them so bitter a feeling of hatred and discontent, that nothing but the opportunity was wanting to blow into a flame the smouldering fires of rebellion. In 1810 that opportunity occurred, when the mother country was overrun by the armies of France, and no longer able to vindicate her own claims to a national existence. In July of that year the Chilenos took the first step towards asserting their independence by deposing the president Carrasco. A junta, which was then formed, assumed the government, with the expressed intention of conducting it according to the old system. Their real design, at first kept secret, was to declare their independence, and to separate entirely from the mother country on the first favourable opportunity.

In April 1811 the first blood was spilt in the cause of Chilean independence. On the day appointed for the election of members to the National Congress, the Spanish rulers attempted to overawe the leaders and people of Chile, of whose dissatisfaction with their government they were fully conscious. A battalion of royal troops, which had been drawn up in the great square of Santiago, was attacked by a detachment of patriot grenadiers, and routed after considerable loss of life on both sides. In the same year, Don Juan Jose Carrera, a young man of great talents and promise, was nominated by the junta supreme president of the Congress which was now convened, and was at the same time appointed general-in-chief of the army about to be formed.

Hostilities were commenced by the Spanish troops who were sent from Lima, Coquimbo, and Chiloé. In the skirmishes that took place during the early part of the contest, the Chilean troops had generally the advantage.

In 1813 a powerful army, under the command of General Paroja, invaded Chile, but was twice defeated by the republican troops under Carrera. The royalists, however, speedily received large reinforcements; and after a severe contest, Chile was once more obliged to own for a time the sovereignty of Spain. For three years the people submitted to the old system of tyranny and misgovernment, till at length the patriot refugees, having levied an army in La Plata, and received the support of the Buenos Ayreans, marched against the Spaniards, and completely defeated them at Chacabuco in 1817.

The patriots next proceeded to organize an elective government, of which San Martin, the general of the army, was nominated the supreme director. Their arrangements, however, were not completed when they were attacked once more by the royalists, and routed at the battle of Chancharayada with great loss. Betrayed into a fatal security by this success, the royalist troops neglected the most ordinary military precautions; and being suddenly attacked by the patriots in the plains of Maipû, were defeated with great slaughter. It is believed that not more than 500 men escaped from the field of battle. This victory secured the independence of Chile.

The new republic had no sooner vindicated for itself a place among the nations of South America, than it resolved to assist the neighbouring state of Peru in achieving a similar independence. This object it at last effected after a bloody war of six years' duration. No small share of this success, however, is to be attributed to the ability with which Lord Cochrane conducted the naval affairs.

Till 1823 General O'Higgins held the chief directorship at Santiago, but in that year he was compelled to resign in consequence of a popular tumult. For a few weeks, a provisional triumvirate discharged the duties of an executive government. General Freire was next chosen director. During the period of three years in which he held the reins of government, the country was harassed by constant dissensions; and for the four years subsequent to his resignation continued in a state of disorder bordering upon anarchy. From 1826 to 1830 the government was administered by no fewer than six different directors, in addition to a second provisional triumvirate.

In 1828, under the administration of General Pinto, a constitution was promulgated, which had the effect of temporarily reconciling political differences, and calming party spirit.

In 1831, however, when General Prieto was raised to the chief magistracy, a convention was called for the purpose of revising this constitution. The result of its deliberations was the present constitution of Chile, which was promulgated on the 25th of May 1833. Since this period Chile has enjoyed remarkable prosperity; its government has been administered with firmness and regularity, and it has assumed a position among the nations; for, aided by the counsels of his prime minister Portales, General Prieto completely succeeded in restoring order, and in promoting the material prosperity of the republic.

After holding office for ten years, Prieto retired, and was succeeded by General Bulnes, a very distinguished officer of the war of independence. Like his predecessor, he was fortunate in finding an able and intelligent minister to counsel and assist him. Manuel Montt was to him what Portales had been to Prieto, and under his guidance Chile continued its onward march in the path of peaceful prosperity.

The insurrectionary movements which took place in Europe in 1848 extended their influence even to the west-

Chile. ern shores of South America. Imitating the anarchists in Europe, the revolutionists formed clubs, selected emblems, and displayed banners. Their irritation was increased by the fact that for twenty years they had been deprived of all participation in the government. When the time for the presidential election of 1851 approached, they brought forward, as candidate for the presidency, Ramon Errazaris, who had formerly belonged to the conservative party, and who was in every way unfitted for the post to which they wished to advance him. The violence of their measures at length led to serious outbreaks in the province of Aconcagua and the town of Santiago. The government at once took vigorous measures to suppress the disturbances. These places were declared in a state of siege, and order was soon restored.

In 1851 the country still continued in a very agitated condition. General Urriola assumed the direction of the insurrectionary movement. On the 20th of April serious disturbances broke out at Santiago during the solemnities of the holy week, which were not quelled without considerable loss of life. The insurgent chief himself was accidentally killed.

The extreme liberal party next brought forward, as a candidate for the presidency, General Jose Mana de la Cruz, in opposition to Don Manuel Montt, the celebrated minister of the former president. The revolutionary party used every exertion to secure the election of their representative, but Montt was chosen president by the almost unanimous suffrages of the people. Enraged at this result, the revolutionary party resolved to throw every obstacle in the way of his regular inauguration. Insurrection was excited by their agents in the provinces of Coquimbo, Copiapo, and Valparaiso. The south was the principal seat of disturbances; and Serena, the capital of Coquimbo, was in the hands of the insurgents. General Bulnes, the former president, was appointed commander-in-chief. Having met the army of the insurgents at Longomilla, he gained a complete victory over them. A capitulation was then agreed to, the result of which was the full acknowledgement of the established government.

The year 1852 commenced with happier auspices than the former. Peace and prosperity were restored to the country by the firmness and decision of the authorities, aided by the good sense of the general body of the people, who had remained faithful to the cause of order. On the opening of the new Congress in the month of June, the greatest confidence was felt in the wisdom and ability of the government, and the people looked forward to a period of renewed prosperity, which has happily not yet been interrupted. (C. B. B.)

CHILIAD (χιλιας), a thousand; a collection or sum containing a thousand individuals or particulars. Also the period of a thousand years.

CHILIAGON, in *Geometry*, a regular plane figure of a thousand sides and angles.

CHILKA, a lake in Hindustan, at the N.E. extremity of the Northern Circars, which province it separates towards the sea from that of Cuttack. It is about 35 miles in length by 10 or 12 in breadth, and appears to have originated in a breach of the sea over a flat sandy shore. The border of sand, about a mile broad, which separates it from the sea, is not visible, so that the lake has the appearance of a deep bay. It is very shallow, and contains several inhabited islands. On the N.W. it is bounded by a ridge of mountains, forming a continuation of those which extend from the Mahanuddy to the Godavery river, and inclose the Northern Circars towards the continent. It is 40 miles S.W. of Cuttack. The lake communicates with the sea by a narrow outlet, in W. Lat. 19. 42. E. Long. 85. 40.

CHILLAMBARAM PAGODA is situated on the sea-coast of the Carnatic, 8 miles S. of Porto Novo, and 120 S.S.W. of Madras, and is held in high veneration by the Hindus. This structure extends 1332 feet by 936, and is entered by a lofty gateway under a pyramid 122 feet high, built of enormous stones, 40 feet long by five feet, and covered with ornamented plates of copper. In 1781 Sir Eyre Coote made an unsuccessful attack on a garrison in this pagoda, belonging to Hyder, who was defeated a few days after with great loss. E. Long. 79. 45., N. Lat. 11. 27.

CHILLIANWALLA, a town in the Punjaub, Hindustan, on the left bank of the river Jhelum. This place is memorable as the scene of a sanguinary battle fought there on the 13th January 1849, between a British force commanded by Lord Gough, and the Sikh army under Shere Singh. The Sikhs are acknowledged to have displayed extraordinary bravery and skill; nor was there wanting conspicuous gallantry on the part of the British; but though the latter remained masters of the field, victory had been purchased by a fearful sacrifice. The loss of the British amounted to 26 European officers and 731 men killed; 66 officers and 1446 men wounded, making a total of 2269, of whom nearly 1000 were Europeans. The loss of the Sikhs was estimated at 4000. Very severe comments were at the time made on the alleged levity displayed by the British general in having suddenly and apparently capriciously changed his plan of operations, and in suffering himself to be provoked by a few stray shots from the enemy's guns to commence the engagement without due precautions, the result being the above stated calamitous loss. An obelisk erected at Chillianwalla by the British government preserves the names of the officers and men who fell in the action. The town is 85 miles N.W. of Lahore. Lat. 32. 40., Long. 73. 39.

CHILLICOTHE, a city in the state of Ohio, North America, capital of the county of Ross, on the W. bank of the river Scioto, 37 miles S. of Columbus. It is pleasantly situated and well laid out, the streets crossing each other at right angles. It has many fine buildings, and is a place of considerable trade and manufactures. The Ohio canal and several railways pass through the town. Pop. 7098.

CHILLINGWORTH, WILLIAM, an eminent divine of the church of England, was born at Oxford in 1602, and educated at Trinity College, of which he was elected a fellow in 1628. He early made great proficiency in his studies, and distinguished himself especially in divinity, mathematics, and versification. During his residence at the university the controversy between the church of England and that of Rome formed the principal subjects of study and conversation, especially in relation to the king's marriage with Henriette, daughter of Henri IV. king of France: and Chillingworth, chiefly at the instigation of the Jesuit Fisher, was induced to abandon the communion of the Church of England and embrace the Roman Catholic faith. Laud, then bishop of London, hearing of this decisive step, and of his retreat to Douay, corresponded with him on the subject and induced him to return to Oxford and re-examine the whole question. This new inquiry resulted in his return to his former faith. In 1634 he wrote a confutation of the arguments which had induced him to join the communion of the Church of Rome; but, at the same time, the freedom with which he spoke of his difficulties gave rise to a groundless report that he had turned Catholic a second time, and then Protestant again. His return to the communion of the Church of England attracted a large share of public attention, and engaged him in controversy with several distinguished Jesuits. In 1635 he engaged in a work designed as an answer to a book entitled *Charity Mistaken*, by a Jesuit of the name of Mathias Wilson, which furnished him with a better opportunity of confuting the principles of the Church

of Rome, and of vindicating the Protestant religion. It was published under the title *The Religion of Protestants a safe Way to Salvation.* About the same time Sir Thomas Coventry, lord keeper of the great seal, offered him preferment; but Chillingworth declined to accept it, on the ground of his scruples with regard to the subscription of the thirty-nine articles. These, however, he ultimately surmounted; and being promoted to the chancellorship of the church of Sarum, with the prebend of Brixworth in Northamptonshire annexed to it, he complied with the usual subscription. Chillingworth was zealously attached to the royal party; and, in August 1643, was present in Charles's army at the siege of Gloucester, where he suggested and directed the construction of certain engines for assaulting the town. Soon afterwards, having accompanied Lord Hopton, general of the king's forces in the west, to Arundel Castle in Sussex, he was taken prisoner by the parliamentary forces under the command of Sir William Waller, who compelled the garrison to surrender. A sudden illness necessitated his separation from the troops who were returning to London, and he was removed to Chichester, where he died in 1644. His character has been delineated by Anthony Wood, by Archbishop Tillotson, and by Lord Clarendon. His theological and controversial pieces have been often reprinted, and form standard works on the subjects of which they treat.

CHILO, one of the Seven Sages of Greece, and one of the ephori of Sparta, the place of his birth, flourished B.C. 590. He was accustomed to say that three things were very difficult—to keep a secret, to know how best to employ time, and to suffer injuries without murmuring. According to Pliny, it was he who caused the short sentence "*Know thyself*" to be inscribed in letters of gold on the temple of Delphi. It is said that he died of joy while embracing his son, who had been crowned as victor at the Olympic games. The institution of the ephoralty has by some been ascribed erroneously to this sage.

CHILOË, an island on the W. coast of South America, separated from the mainland by the gulf of Ancud, and forming with several smaller islands a province of Chile. See CHILE.

CHILTERN HUNDREDS, a hilly district extending through part of Buckingham and Oxford shires. To this district is attached a nominal office in the gift of the crown, and the person holding it is called the Steward of the Chiltern Hundreds. In former times the steward of these hundreds was an officer appointed by the crown to keep the peace there. As a member of the House of Commons cannot, strictly speaking, resign his seat, he may accomplish that object indirectly by accepting a nominal office under the crown, such as the stewardship of the Chiltern Hundreds.

CHIMÆRA, in *Grecian Fable*, a celebrated three-headed monster, sprung from Echidna and Typhon. The fore part of its body was that of a lion, the middle that of a goat, and the hinder part that of a dragon. It is generally depicted as vomiting forth flames; hence Horace—

——— "*Tremendæ*
Flamma Chimæræ."

This monster inhabited Lycia in the reign of Iobates, by whose orders Bellerophon, mounted on the horse Pegasus, overcame it.

The origin of the fable is most probably connected with the volcano of this name in Lycia, the summit of which was a desolate wilderness and the resort of lions; the middle fruitful and covered with goats; while the marshy ground at the bottom abounded with serpents. Bellerophon is said to have conquered the chimæra because he destroyed the wild beasts on that mountain, and rendered it habitable. Plutarch refers it to some pirates who adorned their ships with the images of a lion, a goat, and a dragon. From this fable is derived the term *chimæra* applied figuratively to any wild or incongruous fancy arising in the mind.

CHIMBORAZO, a celebrated mountain of the Equatorial Andes, in S. Lat. 1. 30., W. Long. 79., and long considered the highest in the known world. It is 21,424 feet high. It was ascended by Humboldt and Bonpland in June 1802 to the height of 19,286 feet; and again by Boussingault in December 1831 to 19,689 feet.

CHIME (Danish *kimer*, to tinkle or toll as a bell), the sound of musical bells struck with hammers; or a set of musical bells struck by hammers acted on by a pinned cylinder or barrel, which is made to revolve by clock-work. These are frequently attached to time-pieces, and so arranged as to produce chimes or tunes at stated intervals.

CHIMNEY (French *cheminée*, from Lat. *caminus*, or Gr. *κάμινος* a forge or fire-place), a structure of brick or stone, containing a funnel or funnels to carry off smoke or other volatile matter from the hearth or fire-place where fuel is burned.

As the subject of chimneys is fully treated both in a theoretical and a practical point of view in other parts of this Encyclopædia, we shall here confine our observations to the historical portion of the subject. (See FURNACE; PNEUMATICS; SMOKE; STOVES; BUILDING.)

Chimneys are of modern invention, and were only introduced into England in the reign of Elizabeth, though it appears they were employed in Italy considerably earlier. Octavio Ferrari, however, endeavours to prove that they were in use among the ancients. On this subject Beckmann has written an elaborate dissertation, from which we extract some observations, in order to show the grounds on which he founds his opinion that this convenience is of modern invention.

When the triumviri, says Appian, caused those whom they had proscribed to be sought for by the military, some hid themselves in wells, and others, as Ferrarius translates the words, in *fumaria sub tecto, qua scilicet fumus e tecto evolvitur.* The true translation, however, in Beckmann's opinion, is *fumosa cœnacula.* The principal persons of Rome endeavoured to conceal themselves in the smoky apartments of the upper story under the roof, which in general were inhabited only by poor people; and this seems to be confirmed by what Juvenal expressly says, *Rarus venit in cœnacula miles.*

Those passages of the ancients which speak of smoke rising up from houses, have with equal impropriety been supposed to allude to chimneys. Seneca says, "Last evening I had some friends with me, and on that account a stronger smoke was raised; not such a smoke, however, as bursts forth from the kitchens of the great, and which alarms the watchmen, but such an one as signifies that guests have arrived." The true sense of these words undoubtedly is, that the smoke forced its way through the kitchen windows. Had the houses been built with chimney funnels, there could be no cause for alarm; but as the kitchens had no convenience of that nature, an apprehension of fire, when extraordinary entertainments were to be provided, seems to have been well founded; and on such occasions people were stationed in the neighbourhood to be constantly on the watch to extinguish the flames in case a fire should happen. There are to be found in Roman authors many other passages of a similar kind; such as that of Virgil,

Et jam summa procul villarum culmina fumant;

and the following words of Plautus, descriptive of a miser:

Quin divûm atque hominum clamat continuo fidem,
Suam rem periisse, seque eradicarier,
De suo tigillo fumus si qua exit foras.

Aristophanes, in one of his comedies, introduces his old man, Polycleon, shut up in a chamber, whence he endeavours to escape by the *chimney.* This passage may readily be explained, when we consider the illustration of the scholiasts, by a simple hole in the roof, as Reiske has supposed; and in-

deed this appears to be the more probable, as we find mention made of a top or covering (τηλια) with which the hole was closed.

It has been said that the instances of chimneys remaining among the ruins of ancient buildings are few, and that the rules given by Vitruvius for building them are obscure; but it appears that there exists no remains of ancient chimneys, and that Vitruvius gives no rules, either obscure or perspicuous, for building what, in the modern acceptation of the word, deserves the name of a chimney.

The ancient mason-work still to be found in Italy does not determine the question. Of the walls of towns, temples, amphitheatres, baths, aqueducts, and bridges, there are some, though very imperfect remains, in which chimneys cannot be expected; but of common dwelling-houses none are to be seen, except at Herculaneum, and there no traces of chimneys have yet been discovered. The paintings and pieces of sculpture which are preserved afford as little information, for nothing can be perceived in them which bears the smallest resemblance to a modern chimney.

If there were no funnels in the houses of the ancients to carry off the smoke, the directions given by Columella, to make kitchens so high that the roof should not catch fire, were of the utmost importance. An accident of the kind, which the author seems to have apprehended, had almost happened at Beneventum, when the landlord who entertained Mæcenas and his company was making a strong fire in order to get some birds the sooner roasted.

——————— Ubi sedulus hospes
Pæne arsit, macros dum turdos versat in igne;
Nam vaga per veterem dilapso flamma culinam
Vulcano summum properabat lambere tectam.

Had there been chimneys in the Roman houses, Vitruvius certainly would not have failed to describe their construction, which is sometimes attended with considerable difficulties, and which is intimately connected with the regulation of the plan of the whole edifice. He does not, however, say a word on the subject; neither does Julius Pollux, who has collected with great care the Greek names of every part of a dwelling-house; and Grapaldus, who in later times made a collection of the Latin terms, has not given a Latin word expressive of a modern chimney.

Caminus, as far as we have been able to learn, signified first a chemical or metallurgic furnace, in which a crucible was placed for melting and refining metals; secondly, a smith's forge; and, thirdly, a hearth on which portable stoves or fire-pans were placed for warming the apartment. In all these, however, there appears no trace of a chimney. Herodotus relates, that a king of Libya, when one of his servants asked for his wages, offered him in jest the sun, which at that time shone into the house through an opening in the roof, under which the fire was perhaps made in the middle of the edifice. If such a hole must be called a chimney, our author admits that chimneys were in use among the ancients, especially in their kitchens; but it is obvious that such chimneys bore no resemblance to ours, through which the sun could not dart his rays upon the floor of any apartment.

However imperfect may be the information which can be collected from the Greek and Roman authors respecting the manner in which the ancients warmed their apartments, it nevertheless shows that they commonly used for that purpose a large fire-pan or portable stove, in which they kindled wood, and, when the wood was well lighted, carried it into the room, or perhaps they filled it with burning coals. When Alexander the Great was entertained by a friend in winter, as the weather was cold and raw, a small fire basin was brought into the apartment to warm it. The prince, observing the size of the vessel, and that it contained only a few coals, desired his host, in a jeering manner, to bring more wood or to fetch frankincense; giving him thus to understand that the fire was fitter for burning perfumes than to produce heat. Anacharsis, the Scythian philosopher, though displeased with many of the Grecian customs, praised the Greeks, because they shut out the smoke, and brought only fire into their houses. We are informed by Lampridius, that the extravagant Heliogabalus caused to be burned in such stoves, Indian spices, and costly perfumes, instead of wood. It is also worthy of notice, that coals were found in some of the apartments of Herculaneum, but neither stoves nor chimneys.

It is well known to every scholar, that the useful arts of life were invented in the East; and that the customs, manners, and furniture of eastern nations, have remained from time immemorial almost unchanged. In Persia, which Sir William Jones seems to have considered as the original country of mankind, the methods employed by the inhabitants for warming themselves have a great resemblance to those employed by the ancient Greeks and Romans for the same purpose. According to De la Ville, the Persians make fires in their apartments, not in chimneys as we do, but in stoves in the earth, which they call *tennor*. "These stoves consist of a square or round hole, two spans or a little more in depth, and in shape not unlike an Italian cask. That this hole may throw out heat sooner, and with more strength, there is placed in it an iron vessel of the same size, which is either filled with burning coals, or a fire of wood and other inflammable substances is made in it. When this is done, they place over the hole or stove a wooden top, like a small low table, and spread above it a large coverlet quilted with cotton, which hangs down on all sides to the floor. This covering condenses the heat, and causes it to warm the whole apartment. The people who eat or converse there, and some who sleep in it, lie down on the floor upon the carpet, and lean with their shoulders against the wall, on square cushions, upon which they sometimes also sit; for the *tennor* is constructed in a place equally distant from the walls on both sides. Those who are not very cold put their feet only under the table or covering; but those who require more heat may put their hands under it, or creep under it altogether. By these means the stove diffuses over the whole body, without causing uneasiness to the head, so penetrating and agreeable a warmth, that I never experienced any thing more pleasant. Those, however, who require less heat let the coverlet hang down on their side to the floor, and enjoy without any inconvenience from the stove the moderately-heated air of the apartment. They have a method also of stirring up or blowing the fire when necessary, by means of a small pipe united with the tennor or stove under the earth, and made to project above the floor as high as is judged necessary; so that, when a person blows into it, the wind, having no other vent, acts immediately upon the fire like a pair of bellows. When there is no longer occasion to use this stove, both holes, that is to say, the mouth of the stove and that of the pipe which conveys the air to it, are closed up by a flat stone made for that purpose. Scarcely any appearance of them is then to be perceived, nor do they occasion inconvenience, especially in a country where it is always customary to cover the floor with a carpet, and where the walls are plastered. In many parts these ovens are used to cook victuals, by kettles placed over them. They are employed also to bake bread; and for this purpose they are covered with a large broad metal plate, on which the cake is laid; but if the bread is thick and requires more heat, it is put into the stove itself." (See *History of Invent* ii. 88.)

Beckmann further observes, that the oldest account of chimneys is to be found in an inscription at Venice, which relates that, in the year 1347, a great many chimneys were thrown down by an earthquake. It would appear, however, that in some places they had been in use for a considerable time before that period; and De Gataris, in his history of Padua, relates, that Francesco de Carraro, lord of Padua, came to Rome in 1368, and finding no chimneys in the inn where he lodged, because at that time fire was kindled in a hall in the middle of the floor, he caused two chimneys like those which had *long* been used at Padua to be constructed by masons and carpenters, whom he had brought along with him. Over these chimneys, the first which had ever been seen at Rome, he affixed his arms, and these still remained in the time of De Gataris, who died of the plague in 1405. (See Stoves.)

CHINA.

China Proper is an extensive country of Eastern Asia, situated on the borders of the Pacific, and extending from 20. (or, if the island of Hainan be included, from 18.) to 41. N. Lat., and from 97. to 123. E. Long. Its length from N. to S. is estimated at 1474 miles, and its greatest breadth from W. to E. at 1355 miles; area, 1,348,870 square miles. It is thus about eight times the size of France, and eleven times that of Great Britain. The coast line is upwards of 2500 miles in length. The Chinese empire, however, comprises a vast extent of territory, lying between 20. and 56. N. Lat., and 70. and 144. E. Long. It comprehends not only China Proper, but also Manchooria, Mongolia, Turkistan, and Thibet, having in all an area of 5,300,000 square miles. It is bounded on the E. and S.E. by the Pacific Ocean with its branches, the Sea of Japan, the Yellow Sea, Chinese Sea, and the Gulf of Tonquin; on the N. for 3300 miles by Asiatic Russia; W. and S.W. by Independent Tartary; and on the S. by Tonquin, Laos, and Birmah.

The name China is unknown in the country itself, but seems to have come to us through the Malays, Hindus, or other Asiatic nations, by whom the terms Chin, Tsin, Tchina, &c., are used to designate this country. It is most probably derived from Tsin, the name of a powerful family in China, whose chief first obtained complete sway over all the other principalities about B.C. 250, and whose exploits rendered him famous in India, Persia, and other Asiatic states. The Chinese themselves have many names to designate the country which they inhabit. One of the most ancient of these is *Tien Hia*, *i.e.*, beneath the sky, meaning the world; another, almost as ancient, is *Sz'Hai*, *i.e.*, (all within) the four seas; a third, and now the most common, is *Chung Kwoh*, or middle kingdom, from an idea that it is situated in the middle of the earth. They also frequently call their country after the name of the reigning dynasty.

The whole surface of China may be divided into the mountainous country, the hilly country, and the Great Plain. This last occupies the N.E. part of the country, extending S. as far as the Yang-tse-kiang, and is about 700 miles in length, with a breadth varying from 150 to nearly 500 miles. Its area is estimated at 210,000 square miles, and it is thus seven times greater than the plain of Lombardy. The most interesting feature of this plain is the enormous population which it contains, amounting, according to the census of 1812, if we take the six provinces that lie wholly or for the most part within it, to 177,000,000 persons, and being thus the most densely populated of any part of the world of the same size. The soil in the northern part is dry and sandy, destitute of trees, but producing millet, wheat, and vegetables in abundance; that lying near the coast in Kiang-su is low and swampy, covered with numerous lakes, and intersected by many water-courses. This portion of the plain is extremely fertile, and furnishes large quantities of silk, tea, cotton, grain, and tobacco for the consumption of the other provinces. Proceeding inland, the soil becomes more dry and firm, but is well watered and fertile. The eastern portion of the plain is traversed by the Grand Canal, which serves not only to facilitate communication, but also to drain and irrigate the adjacent country.

The mountainous region comprehends more than one-half of the whole country, and may be said to extend from the meridian of 112°, and N. of the Yellow River from that of 114°, westward to the borders of Thibet. All this immense tract of country is covered by mountains and valleys; the former usually steep and rugged, the latter watered by numerous streams, and very fertile. The mountain chains which constitute the eastern edge of the high table-land of Eastern Asia, lie within the western boundary of China. These chains send off several branches eastward, which gradually subside into low hills as they proceed towards the coasts. The chief of these are the Nan-ling, or southern mountains, and the Pe-ling, or northern mountains. The Nan-ling, which constitutes the most extensive mountain system in China, branches off from the northern edge of the Yun-nân highlands, and runs eastwards, passing about 150 miles to the N. of Canton; it then takes a north-eastern direction through Fokien, and terminates in Che-keang. N. of Canton is the Mei-ling Pass, by means of which goods are transported from Canton to the interior of China. The second principal chain of mountains is the Pe-ling, which passes eastward through the provinces of Shen-see and Honan to about 113. E. longitude, when it turns to the S.E., and soon after terminates in a range of hills. Each of these chains send off numerous offshoots in different directions. Many of the mountains in the W. of China reach the limit of perpetual snow.

The hilly portion of the country lies to the E. of 112. E. longitude, and S. of the Yang-tse-kiang. It constitutes the most picturesque portion of China; the hills having generally gently sloping sides, which are carefully cultivated, while their summits are crowned by plantations. They are frequently laid out in terraces for the cultivation of rice. The valleys between the hills in some places expand into considerable plains.

The rivers of China are her chief glory, and it is to them principally that she is indebted for that fertility of soil by which she is enabled to maintain her vast population. The principal of these are the Hoang-ho, or Yellow River, and the Yang-tse-kiang, which rank among the greatest rivers in the world. They both rise in the high table-lands of Eastern Asia, pursue tortuous but generally easterly courses, and, though at one time their waters are more than 1100 miles apart, they discharge themselves into the sea within about 110 miles of each other. They are respectively about 2500 and 3000 miles in length, and have each a great number of affluents. Besides these there are an immense number of other rivers which fall into the sea or into lakes.

The lakes of China are numerous, but few of them are of great extent. The largest is the Tong-ting-hou, which is about 220 miles in circuit. It receives the waters of many considerable rivers, and discharges itself into the Yang-tse-kiang. The Po-yang-hou, another lake of great

dimensions, which discharges its surplus waters into the Yang-tse-kiang, is noted for the beauty of its surrounding scenery. All the lakes and rivers are well stocked with fish.

The coast of China, S. of the promontory of Shan-tung, is generally bold and rocky, except at the points where the Yellow River and the Yang-tse-kiang empty themselves into the sea. The province of Pekin is a sandy flat, and the gulf which skirts it is extremely shallow, so that large ships cannot approach within many miles of the shore. The whole coast is said to abound in safe and commodious harbours.

As to the origin of the Chinese, various hypotheses have been given out by different authors. By De Guignes and Fréret, arguing from the communications of the Jesuits, they were supposed to be derived from a colony of Egyptians; by the earlier Jesuits they were set down as a tribe of the Jews; and by Sir William Jones as the descendants of the Cshantrya or Military Caste of Hindus, called Chinas, "who," say the Pundits, "abandoned the ordinances of the Veda, and lived in a state of degradation." With submission to such high authorities, we should as soon think of deriving the trunk of a tree from its branches, as the people of China from any of these. That they are not Egyptians, the ingenious Pauw has most clearly and satisfactorily demonstrated, by proving that in no one iota does there, or ever did there, exist one single resemblance. As little similarity is there between them and the Hindus: no two people, indeed, could possibly differ more than they do in their physical and moral character, in their language, and in their political and religious institutions. The colour of the Hindu is ebon black or a deep bronze, that of a Chinese a sickly white or pale yellow, like that of a faded leaf, or a root of rhubarb; the features of a Hindu are regular and placid, those of a Chinese wild and irregular, constant only in the oblique and elongated eye, and the broad root of the nose; the Hindus are slaves and martyrs to religious ordinances, the Chinese have superstitions enough, but, strictly speaking, no religious prejudices; the Hindus are divided into castes, the Chinese know of no such division; the historical records of China go far beyond the time that these supposed Chinas of Sir William Jones peopled the country, the Hindus have not a page of history; the language of Hindustan is alphabetic, that of China a transition from the hieroglyphic to the symbolic, and there is not the slightest analogy in the colloquial languages of the two countries.

Dr Marshman has set the question, as to any similarity between the Sanscrit and Chinese languages, completely at rest. The priests of Buddh, who were permitted to enter China in the first century of the Christian era, endeavoured, with their religion, to introduce the Sanscrit alphabet, or series of sounds represented by the Devanagari character; and this series being placed at the head of Canghe's Dictionary, induced Dr Marshman to suppose that there might be some connection between the Chinese and the Sanscrit languages. Had he, however, read the preface to that dictionary, he would have seen that the compilers announce it as a system brought from the West, which the learned of China could never be prevailed on to adopt. This Hindu series of alphabetic sounds did not, however, mislead him; he was fully aware that a pure, unchangeable, monosyllabic language could not arise out of a polysyllabic one; that a language which admitted of no change from its original monosyllabic root, but retained it in its primitive form, whether employed as a noun, a verb, or a participle, could not have been derived from another language whose dhatoos or roots, by a complicated mechanism, assumed a hundred different shapes; nay, whose inflections, in some instances, are so numerous, as to produce more than a thousand modifications of an idea from one radical word. In addition to all this, when he reflected that there were in the Sanscrit alphabet four or five sounds which the organs of a Chinese could not by any possibility enunciate, he found it utterly incompatible to associate the two languages together, and was confirmed in his idea by the test of facts. He took the Ramayuna, which is supposed to be the most ancient poetry in the Sanscrit language, and the *Shee-king* of the Chinese. In ten pages of the former, containing four hundred and fifty-nine words, he found only thirteen monosyllables, and of these thirteen, seven do not occur in the *Shee*, nor are any two of them used to express the same idea in both languages. He next took four pages of the Mahabharu, in the Bengalee dialect, containing two hundred and sixty-five words, in which he found only seven monosyllables, and of these, *three* only were Chinese.

Proceeding in the same manner, he proves, what was scarcely necessary, that there exists not the most distant resemblance between the Chinese and the Hebrew languages. In examining the speech of Judah to Joseph, in the 44th chapter of Genesis, he finds it to contain two hundred and six words, in which there occur sixteen monosyllables; but of these, seven only are Chinese words. In Abraham's intercession for Sodom, out of two hundred and thirty words, ten only are monosyllables, and of these, four are Chinese. Again, in the maledictory prophecy of Noah, relative to his grandson Canaan, in twenty-six words there is but one monosyllable. It would be most absurd, therefore, to conclude that the Chinese derived their language from the Hebrew, when one word only occurs out of twenty-nine, as in the first example, one out of fifty, as in the second, or one in twenty-six, as in the third; and he thinks it more rational to infer, that as it is neither derived from the Sanscrit nor the Hebrew, it is an original language invented by themselves. Neither is there any resemblance to be found in the manners, customs, physical character, or religious creeds, of the two people. There is, in fact, a colony of Jews in China, whose entrance can be traced beyond the Christian era; who use the Hebrew language; who abstain from swine's flesh, the great article of Chinese food; use circumcision, and celebrate the passover, neither of which the Chinese know anything about; and it may, therefore, fairly be concluded that they are neither Jews, Hindus, nor Egyptians, but an original people, who have kept themselves more unmixed with other nations than any people existing on the face of the earth. (Barrow's *Travels in China;* Marshman's *Clavis Sinica.*)

Probable origin.

Pauw, and some other writers, are of opinion that they proceeded originally from the heights of Tartary. It is, in fact, obvious enough that the Tartars and Chinese are one and the same race; and the only question seems to be, whether the latter, guided by the mountain-streams, descended from the bleak and barren elevations of Tartary, which, bulging out of the general surface of the earth, have been compared with the boss of a shield, to the fertile plains and temperate climate of China; or, whether the former are swarms sent off by an over-abundant population, and driven into the mountains. The former supposition will be regarded, perhaps, as the more probable of the two. In all the institutions which the change from a pastoral to an agricultural state would necessarily require, the ancient manners and customs of the Hyperborean Scythians, as described by Herodotus, are still discernible among the Chinese. A Chinese city is nothing more than a Tartar camp, surrounded by mounds of earth, to preserve themselves and cattle from the depredations of neighbouring tribes, and the nocturnal attacks of wolves and other wild beasts; and a Chinese habitation, the Tartar tent, with its sweeping roof supported by poles, excepting

that the Chinese have cased their walls with brick, and tiled the roofs of their houses. When the famous barbarian Gengis-khan made an irruption into the fertile plains of China, and took possession of a Chinese city, his soldiers immediately set about pulling down the four walls of the houses, leaving the overhanging roofs supported on the wooden columns, by which they were converted into excellent tents for themselves and horses. Yet such is the facility with which Chinese and Tartars amalgamate, that although this celebrated barbarian could neither read nor write any language, he listened to the advice of the conquered, became sensible of the change of situation in which he found himself, did every thing he could to repair the errors he had committed, and both he and his successors left good names behind them in the annals of the country. In like manner, the present Mantchoo Tartars, who lived in tents, and subsisted on their cattle and by hunting, immediately accommodated themselves to the manners, the customs, and the institutions of China, preserving nothing of their own, not even their religion, and scarcely a vestige of ancient superstitions, that does not coincide with those of the Chinese—one of the most singular of which is, their agreement in the birth of man and of the serpent-woman, and the universal use and estimation of the ancient Scythian emblem of the dragon. Next to the Chinese, the Turks seem to have preserved most of the character and customs of the ancient Scythians from whom they sprung; and the Turks are Tartars. Some German author has pointed out a similarity between the Turks and Chinese in seventeen different customs; he might have extended the parallel to more than twice that number. (*Recherches sur les Chinois*, par M. de Pauw.)

Antiquity and history.

It has long been objected in Europe against the authenticity of the early part of Chinese history, that it abounds with absurd fictions and irreconcilable contradictions, and that it sets up a chronology and cosmogony at variance with the sacred writings, and the generally received opinions of mankind. This, however, is not the fact with regard to Chinese history in its pure and original state, divested of the reveries of Fo or Buddh, which the priests of this sect imported with their religion, and found means to propagate among the vulgar. The Hindu periods of the creation and destruction of the universe,—the miraculous conceptions, and all the absurd stories of gods, demi-gods, and heroes, are scouted by the learned of China. The period they assign for the commencement of their civilization is perfectly consistent with the time when, according to holy writ, the great catastrophe befel the earth; and though they are unable to establish the truth of the early part of it by any concurring contemporaneous histories of other countries, yet neither can any extraneous authority be produced to contradict theirs; the probability, therefore, of the truth or falsehood must rest on the internal evidence of their own history, and the manner in which that history has been compiled, preserved, and handed down to posterity.

We may take it for granted, that when the Emperor Kaung-hee summoned to Pekin the most learned men of the empire, for the purpose of translating into the Mantchoo language an abridged history of China, from the earliest times, those annals only were consulted which were considered as most authentic, namely, those which are compiled and published by the college of *Han-lin*. Père Mailla was one of those missionaries who viewed the Chinese less through the eye of prejudice than most of the Jesuits. He was employed by the emperor in making a survey of the empire, which cost him and his colleagues the labour of ten years; he passed forty-five years of his life in the country, and generally about the court, during which time he made himself perfectly acquainted with the Mantchoo and the Chinese languages. When, therefore, Kaung-hee undertook the laudable design of giving to his Mantchoo subjects an authenticated history of China in their own language, Père Mailla conceived the idea of proceeding *pari passu* with a translation of the same work into French; and having lived to complete this Herculean labour, it was published at Paris, after many difficulties and delays, by the Abbé Grozier, in fourteen large quarto volumes, under the title of *Histoire Générale de la Chine*.

The history of China commences, in fact, at a period not much more than 3000 years before the birth of Christ, by describing the little horde from which the Chinese had their origin, to be in as barbarous and savage a state as can well be imagined; roving among the forests of *Shen-see*, just at the foot of the Tartar Mountains, without houses, without any clothing but the skins of animals, without fire to dress their victuals, and subsisting on the spoils of the chase, on roots and insects. Their chief, of the name of *Yoo-tsou-she*, induced them to settle on this spot, and they made themselves huts of the boughs of trees. Under the next chief, *Swee-gin-shee*, the grand discovery of fire was effected by the accidental friction of two pieces of dry wood. He taught the people to look up to *Tien*, the great creating, preserving, and destroying power; and he invented a method of registering time and events, by making certain knots on thongs or cords twisted out of the bark of trees. Next to him followed *Fo-hee*, who separated the people into classes or tribes, giving to each a particular name; discovered iron; appointed certain days to show their gratitude to heaven, by offering the first fruits of the earth; and invented the *Ye-king* or *Koua*, which superseded the knotted cords. Fo-hee reigned 115 years, and his tomb is shown at Tchin-choo, in the province of Shen-see, at this day. His successor, *Chin-nong*, invented the plough; and from that moment the civilization of China proceeds by rapid but progressive steps.

As the early history of every ancient people is more or less vitiated by fable, we ought not to be more fastidious or less indulgent towards the marvellous in that of China, than we are towards Egyptian, Greek, or Roman history. The main facts may be true, though the details are incorrect; and though the accidental discovery of fire may not have happened under Swee-gin-shee, yet it probably was first communicated by the friction of two sticks, which at this day is a common method among almost all savages of producing fire. Nor is it perhaps strictly correct that Fo-hee made the accidental discovery of iron, by having burnt a quantity of wood on a brown earth, any more than that the Phœnicians discovered the mode of making glass by burning green wood on sand; yet there is nothing improbable, either in the one or the other, that these two processes first led to the discovery of both. And if it be objected against the history, that the reign of a hundred and fifteen years exceeds the usual period of human existence, it should be recollected, at the same time, that such an instance is as nothing, when compared with those contemporaneous ones recorded in biblical history. Thus, also, considerable allowances are to be deducted from the scientific discoveries of Chin-nong in botany, when we read of his having in one day discovered no less than seventy different species of plants that were of a poisonous nature, and seventy others that were antidotes against their baneful effects.

The next sovereign, Hoang-tee, was an usurper; but during his reign the Chinese are stated to have made a very rapid progress in the arts and conveniences of civilized life; and to his lady, See-ling-shee, is ascribed the

honour of having ﬁrst observed the silk produced by the worms, of unravelling their coccoons, and working the fine filaments into a web of cloth. The tomb of Hoang-tee is also kept up to this day in the province of Shen-see.

From these few recorded facts, out of a multitude stated by Chinese historians, we think it may be inferred that, at a very distant period, and at the earliest dawn of civilization, a small horde of Tartars, descending from their elevated regions, seated themselves on the plains of Shen-see, at the foot of the mountains; and, under the guidance of a succession of intelligent chiefs, changed the pastoral and venatorial life for one more stationary, and at length became cultivators of the soil, and spread themselves over the fine fertile region now known by the name of China. (*Hist. Gén. de la Chine*, par P. Mailla.)

Authenticity of their history examined.

Some doubts have been entertained with regard to the authenticity of that part of Chinese history which relates to the reign of the first three sovereigns, *Fo-hee*, *Chin-nong*, and *Hoang-tee*, which is supposed to have been contained in a book called *San-fen;* and of the five following reigns, ending with the joint government of *Yao* and *Chun*, as detailed in another work named the *Ou-tien.* Of the first of these works the Chinese avow that nothing is known; and all that remained of the second was an imperfect fragment preserved by being inserted at the head of one of their most ancient and valued books, called the *Shoo-king*, of which we have a translation, or rather a bad paraphrase, by Père Gaubil. This fragment relates chiefly to the reign of *Yao* and *Chun.* The rest of the *Shoo-king* contains an abridged history of the empire, from the joint reign of these two sovereigns down to the time of Confucius, being a compilation by this celebrated sage. The authenticity of the *Shoo-king* must, however, depend on two circumstances; first, whether it is the same that was composed by Confucius; and, secondly, whether the materials which this sage possessed were authentic. If he really had copies of the *San-fen* and *Ou-tien*, the *Shoo-king* may fairly be classed with the history of Herodotus, with whom Confucius was contemporary,—the Chinese historian having the additional advantage of previous written records. But, admitting this to have been the case, there is still an awkward and suspicious chasm in the history of China, the cause of which draws largely on our faith. The Emperor Che-whang-tee, of the dynasty of *Tsin*, after reducing into subjection the provinces which had revolted, conceived the mad scheme of destroying all the writings of the empire, under the idea of commencing a new set of annals with his own reign, in order that posterity might consider him as the founder of the empire. Some sixty years after this barbarous decree had been carried into execution, his successor, desirous, as far as might be possible, to repair the injury, held out great rewards to those who could produce any part of the annals of the empire, more especially the hundred chapters of the *Shoo-king.* After some time, a copy of the *Shoo-king* was procured in this manner. All ancient writings, and those of Confucius in particular, were comprised in short sentences, forming a kind of poetry, not unlike the Proverbs of Solomon; and they were in the memory of most persons then, as they are now, who had any pretensions to literature; but sixty years having been suffered to elapse before any encouragement was held forth for the revival of letters, most of those who had known the *Shoo-king* were either dead, or so old as to have lost the recollection of it. At length, however, a man named Foo-seng, of the age of ninety and upwards, was discovered, who, in earlier life, could repeat the whole of the *Shoo-king* by heart. To this man the historiographers of the empire were sent; but he was unable to write, and his articulation was so imperfect, that the parts of it which he recollected could only be obtained through the medium of his daughter, who, having received the words from her father, repeated them to the historians. In this way they proceeded until twenty-nine of the books or sections of the *Shoo-king* had been committed to writing, which Foo-seng had comprehended in twenty-five; but here they were compelled to stop, the infirmities of Foo-seng not allowing him to proceed. A document thus obtained did not pass for genuine among the learned; yet all were eager to procure copies of it, in order to compare such passages as each might recollect to have heard their fathers repeat. The early annals of China, however, do not rest solely on this record. Half a century after this, a prince of Loo, in pulling down an old building (some say the house in which Confucius lived), to erect on its site a temple in honour of that philosopher, discovered in one of the walls an imperfect copy of the *Shoo-king*, with two other works of Confucius. They were much devoured by the worms, and written in a character which had gone out of use. The learned men were assembled to collate this newly discovered copy with that taken from Foo-seng's recollection, and it is said that they did not materially differ, except in the division into chapters. They therefore proceeded in deciphering the remaining part of the characters, and, after much time and labour, obtained twenty-nine complete articles, in addition to the twenty-nine recollected by Foo-seng, making the fifty-eight chapters of which the *Shoo-king* at the present day is composed.

The story is told by Chinese writers with some variations; but it is a common saying, that "both the ancient and modern *Shoo-king* were taken from the wall of a house." According to some, the old man Foo-seng hid a copy of the book within the wall of his house, and, to avoid the rigour of the persecution that was carried on against men of letters, put out his own eyes and affected idiotism. The whole story, however, is not very consistent, and it has been conjectured that it was invented as a salvo to the mortified vanity of the Chinese, who were unable to make out a connected series of annals from a high antiquity; and that, in fact, Confucius was the first regular historian of the empire, and probably the person who first led them on rapidly to a state of civilization. One thing at least is perfectly well ascertained; no writings of any description prior to those ascribed to Confucius exist in China. Where the *Shoo-king* terminated, Confucius commenced his own annals, called the *Tchun-iou*, which carried down the history of the empire to his own time; and of this work a copy had been secreted by one of the historiographers. Many other manuscripts were from time to time brought in, from which were selected all that belonged to the history of the empire, by a commission, of which *Tse-ma-tsin* was placed at the head; after his death his son *Tse-ma-tsien* completed this great work, which is still extant, about a century before the Christian era, and its author is considered and known by the name of the *Restorer of History.* From that period to the present time there seems to be no reason to doubt the authenticity of Chinese history, or to accuse it of undue partiality. The history of a dynasty is not made public from authority, until that dynasty has ceased to reign; and it does not appear that any injustice is done or attempted by the succeeding dynasty. Some of the atrocities of Gengis-khan are related on his first incursion into China, but ample justice is done to him and to his successors; and the present Tartar dynasty, in publishing the annals of that of *Ming*, whom they displaced, does not appear to have done it any violent injustice. This event occurred under the eye of several European missionaries then resident in the capital; and, by their concurring testimonies, the affairs of the empire were left, as the Chinese state, to priests,

and eunuchs, and jugglers; and it is favourable to the character of the college of Han-lin, that, for the sake of accuracy, the history of the dynasty of Ming was retarded for some time, by the Chinese members refusing to allow the Tartar race, then on the throne, the title of *imperial*, until the last remaining prince of the family of Ming should be extinct; but the Tartars insisted on dating the commencement of their own dynasty from the day they were in possession of Pekin, to which at length the Chinese members were reluctantly compelled to assent. In the instance of Gengis-khan they were most successful. The name of this marauder does not appear in the list of Chinese emperors, nor those of the two next in succession, Ogdai-khan and Menko-khan, though their exploits are amply detailed in Chinese history. The Mongoo dynasty commences only with Kublai-khan, who was not declared emperor till the death of the last remaining branch of the family of *Song*. Their account of these Tartars is probably very correct. They had neither treasure to pay their troops, nor magazines of provisions for their subsistence. They lived by the chase and by plunder, driving before them large herds of cattle, whose flesh served them for food when other supplies failed, and their skins for clothing. They put to death men, women, and children, without compunction, plundering the towns and villages through which they passed, and carrying off the young women; and when the Chinese took up a strong position in the passes of the mountains, it was the practice of Gengis-khan to seize all the old men, women, and children of the neighbouring country, and drive them forward at the head of his army, and thus, approaching the Chinese under cover of their own friends and relations, succeed in coming upon them without their being able to strike a single blow; and it is added, that, had it not been for the remonstrances of a Chinese who had united his fortunes to those of the invaders, Gengis-khan had determined to put to death all the agriculturists, for ploughing up the ground, and destroying the grass on which his numerous cavalry was to be subsisted.

As their history relates solely to the internal events and transactions of the empire, and as their policy has been to exclude all communication with foreign nations, we have no means of verifying the facts that are related; but it is in favour of their accuracy to find a fact recorded in the progress of a revolution brought about by a change of dynasty, which is also related by an European traveller, who was himself a party in the transaction, and who is worthy of implicit credit in all that he states to have fallen under his own knowledge and observation. Marco Polo states, that *Sian-foo* was taken by the Mongoos after a siege of three years, chiefly by means of machines made by his father and uncle, which hurled stones of three hundred pounds in weight; and it is recorded in the history of China, that the city of Siang-yang held out against the troops of Kublai-khan for four years, but was at length reduced by means of certain machines for hurling stones of an extraordinary weight, constructed by one *Alhaya*, who had travelled to China from the western countries.

Another instance of the fidelity of the Chinese historians is affirmed by the faithful traveller Marco Polo. It is recorded that Kublai-khan adopted the Chinese manners and customs, and gave encouragement to the arts and sciences, commerce and manufactures; that he opened the ports of China to all foreigners; that he sent embassies and expeditions to almost every part of the world, and received tribute from the sovereigns of Pung-kia-la (Bengal), Soo-ma-ta-la (Sumatra), and Mal-la-kia (Malacca); subdued Corea, but failed in his expedition against Japan, or, as they call it, Je-pun-quo, the kingdom of the rising sun; all of which will be found related in Marco Polo, whose accuracy in relating what was told him appears in another Chinese book called *Fo-quo-kee*, a history of the kingdom of Fo, giving an account of the temples of India, visited by a Ho-chang or priest in the fourth century, in which, among other things, is noticed the yells and musical strains made by invisible spirits in the great desert of Sha-moo, to frighten and bewilder the traveller; a fable repeated by Marco Polo, in speaking of the same desert, nine hundred years afterwards. (*Hist. Gen.*; Morrison's *Dictionary*; Marco Polo.)

Government.

But whether the ancient history of China be true or false—whether Yao or Chun were real or fictitious personages, and Confucius the real author of the religious, moral, and political maxims ascribed to these sovereigns, the Chinese at least entertain no doubts on the subject; and on these maxims are all their institutions founded, as we find them existing at the present day. In all these institutions may be discovered the traces of a primeval state of society. The leading features of the government still wear the stamp of the first rude attempts to restrain savage man within the pale of social life; paternal solicitude and protection on the part of the chief, obedience and service on that of the people. The same principles which their history states to have regulated the pastoral tribes of Fo-hee on the plains of Shen-see, four thousand years ago, actuate the measures of the Chinese government of the present day. A few modifications of the ancient patriarchal system have served to convert tribes of hunters and shepherds into a nation of agriculturists, and to keep them so; for of all governments which the history of the world has made known, none has had that permanency and stability which China has enjoyed. Like other governments, the machine may occasionally have been enlarged; a few wheels may have been added, its movements sometimes disturbed, its operations impeded, and a spring or a wheel injured or destroyed; but the damage has soon been repaired, and without altering or improving the principles of the construction. Rebellion, revolution, and foreign conquest, have occasionally removed old families from, and placed new ones on, the vacant throne, and for a moment disturbed the movements of the machine; but a little time has generally restored the usual harmony of its operations. It becomes, therefore, an object of interest to inquire, on what principles, and by what practice, the largest mass of population which in any age or country has been united under one government, has been kept together in one bond of union, for a period of time extending far beyond that at which the history of the earliest European nations may be said to commence. It has assuredly not been owing to the superior virtues of its princes, for China has had its Neros and Caligulas as well as Rome; nor to the superior virtues of the people, for Chinese morality consists more in profession than in practice; and yet the affectation of superior virtues in the one, and of moral sentiment in the other, has gone far in giving support to the system of government, and securing the permanency of the ancient institutions of the country.

Ancient usage, universally appealed to, is almost the only rule of conduct, and the only limitation or control prescribed to the executive authority vested in the monarch. The public voice is never heard, but the public opinion is sedulously courted by the sovereign, and conveyed to every part of the empire through the medium of the *Pekin Gazette*. This vehicle of imperial panegyric is published daily; it is sent forth into all the provinces, and read in all the public taverns and tea-houses. It is one of the most powerful engines of state; and a series of this paper would explain the nature of the government

better than all the moral maxims of antiquity on which it is supposed to be founded. Through it are all the measures of the government, or rather of the sovereign, communicated to the public. If he fasts or feasts, promotes or degrades, levies or remits taxes, feeds the hungry, clothes the naked, rewards virtue or punishes vice, or, in short, whatever laudable action he may perform, it is announced in this state paper, with the motives and the reasons that may have given rise to it. All imperial edicts of a special nature, after being addressed to the proper tribunal or other authority, are promulgated in the *Pekin Gazette.* The papers presented before the General Council, and decided upon or examined by the emperor, are published or noticed in this Gazette, which contains nothing but what relates to the emperor or the supreme government. In the provinces thousands of persons find employment by copying and abridging the Gazettes for readers who cannot afford to purchase the complete edition. To falsify any of the papers therein contained is a crime punishable by death.

The grand leading principle of this patriarchal government is to place the sovereign at as great a distance from the people, and as far removed from mortality, as human invention could suggest. They not only style him the "Son of Heaven," but believe him to be of heavenly descent; and this superstitious notion appeared in a manner sufficiently remarkable, by the obstacles thrown in the way of the present Manchoo dynasty, on account of their family not being able to trace their descent farther back than eight generations; a defect of ancient origin which was considered by the Chinese as a great reproach. Kaung-hee, aware of their prejudices, caused the genealogy of the Tartar family to be published in the Gazette. It stated that "the daughter of heaven, descending on the borders of the Lake Poulkouri, at the foot of the White Mountain, and eating some red fruit that grows there, conceived, and bore a son, partaking of her nature, and endowed with wisdom, strength, and beauty; that the people chose him for their sovereign; and that from him were descended the present Son of Heaven, who filled the throne of China." And this explanation wiped away the reproach, and fully satisfied the subjects of the "celestial empire."

In the capacity of sovereign, the Emperor of China is supposed to sustain two distinct characters. The first is that of a high priest, in which he, and he alone, mediates and intercedes with heaven for all the sins and misdeeds of his people. In this character he alone can officiate at solemn feasts, when Heaven is to be propitiated by suitable oblations. He not only has the merit of all the prosperity that the empire enjoys; but he also affects to consider public calamity as the consequence of some act committed, or some duty neglected by him. When, therefore, insurrections, famines, earthquakes, or inundations, afflict the people, he affects the deepest humility, appears in the meanest dress, strips the palace of its ornaments, and suspends all the court amusements; but even in this state of humiliation he is held up as the peculiar object of heaven's attention, whether it be to punish or to bless.

His second character as sovereign of the empire is that of "the father and mother of his people." In this character it is supposed that his subjects bear the same relation to him that he stands in towards *Tien* or heaven. His ministers or magistrates execute his will, and are supposed to be placed as agents between him and the people, in the same manner as heaven has its agents to regulate the divine decrees on earth; but all power, honour, offices, and emoluments, emanate from him alone, and are revocable at his pleasure. His prerogative is undefined and undivided, unrestrained by any written law, and checked only by ancient custom, stronger even than law. "Heaven," says Confucius, "has not two sons, earth has not two kings, a family has not two masters, sovereign power has not two directors—one God, one emperor," not for China alone, but for all the earth, the rest of the sovereigns being considered as his vassals. This doctrine was boldly avowed on the occasion of Lord Amherst's embassy, when the ceremony of prostration was demanded, not as a mere ceremony, but as the sign and seal of vassalage, and on this ground was of course resisted.

This self-created universal autocrat is not only the fountain of all honour in his wide dominions, but of all mercy. He is held upon all occasions as the mediator for his people, stepping in between the sentence of the law and the execution of it, and with a fatherly tenderness remitting a certain portion of the punishment which the law awards, and which the magistrate has no power to dispense with. If a magistrate instructs the people, it is in the name of the emperor; if he flogs them for a misdemeanour, he remits a certain number of blows as the emperor's grace; he orders his ministers to attend at all times to the complaints of the people; and, that none may be denied access to the chief magistrate of the district, a gong or drum is suspended at the outer gate of his dwelling,—but woe be to him who ventures to sound it without substantial reason; the emperor's grace would not save him from at least a dozen strokes of the bamboo. Navarette says that the judge's drum at Nankin is covered with the hide of an elephant, and the drum-stick, a huge piece of timber, is slung by strong ropes from the roof of the house. This poor Jesuit had a ready credulity to receive all for truth which the Chinese told him.

The name of the sovereign, however, rarely appears but in an amiable light; the people hear of him only as distributing rewards, punishing oppression, relieving the distresses of the poor, opening the public magazines in times of scarcity, and remitting all taxes where the state of the treasury will afford it. Thus it appears, that Kien-lung, having received a report from the board of revenue that a balance remained in the treasury of seventy millions of ounces of silver, issued an edict, by which he exempted all his people from one year's taxes. This is all very good, and so is the whole theory of this arbitrary government, as delivered in the following rescript, which the minister of Timour-khan put into the hands of this sovereign; indeed, were the practice but conformable with it, we might call it truly Utopian. 1. Study with eager attention the will of heaven. 2. Be careful to tread in the steps of your ancestors, and to imitate their virtues. 3. Cease not to show your respect and gratitude to the august parents who gave you birth. 4. Watch over your people with a fatherly fondness. 5. In the exercise of sovereign power preserve an upright heart and an elevated soul. 6. Be moderate in your pleasures. 7. Drink little wine. 8. Do not lavish your treasures. 9. Extend your benefits to men of merit. 10. Make your justice formidable to criminals. 11. Drive from your presence knaves and flatterers. 12. Cherish upright and sincere men, and receive with temper their wise remonstrances. 13. Study the character of those you employ, and proportion their employments to their talents. 14. Regulate your time to your occupations, so that they may suit each other. 15. Let not a day pass without studying the maxims of the ancients. And he concludes by observing, that by putting in practice these fifteen precepts, he would secure to himself a happy reign, and to his people prosperity and the blessings of peace.

In Kaung-hee's declaration on the appointment of his successor, a short time previous to his death, he observes, that "the true way for a sovereign to perform his essen-

tial duty towards heaven and the memory of his ancestors, is to procure for his people peace and plenty; to make his own happiness consist in the happiness of the people, and his own heart the heart of the whole state;" and he adds, "although since I have occupied the throne, I cannot say that I have succeeded in changing the bad customs, and reforming the morals of my people; although I may not have been fortunate enough to give plenty to every family, or the necessaries of life to every individual; yet I may venture to assert, that during my long reign I have had no other view than to procure for the empire a solid peace, and to render all my people satisfied in their respective conditions. During my whole reign I have caused the death of no one without a sufficient reason. I have never ventured upon any useless expense to be defrayed from the public treasury; it is the blood of the people. I have drawn nothing from it that was not necessary for the subsistence of the army, and for relieving the calamities of famine," &c.

The ancient and established maxims of filial piety, form, however, the grand basis of the Chinese government. Every son is supposed to hold the same relation to his father that the people do to the sovereign; and the same unnatural and unwarrantable power which is given to the father over his children could not consistently be withheld from the emperor. No wickedness or unnatural treatment can, on the part of the parent, relieve a son from his duties. The merit of every good action performed by the son is ascribed to the education given to him by the father, but the son bears his own disgrace. In like manner, the sovereign receives the whole merit of the country's prosperity, but his ministers incur the disgrace of all its misfortunes. To be consistent in thus placing the young and vigorous at the mercy of the old and feeble, the emperor affects to pay the same homage and obedience to his mother that are due from children towards their parents. The effect of this state morality, destructive of all real sentiment, is that of rendering every man a slave to some other, and establishing a system of tyranny, which descends in an uninterrupted chain from the emperor down to the meanest peasant. But this is not the worst: every man distrusts his neighbour; because every man is known to assume a character that does not belong to him, and constantly to act the hypocrite in public.

The jealousy and suspicion which prevails, from the sovereign on the throne to the lowest of the magistrates, evince how little they trust to the fine maxims of morality, by which, it is pretended, the throne is supported and the happiness of the people secured. No magistrate, for instance, can hold an employment in a district where he has relations; he cannot marry in that district; he cannot purchase lands in it: if his father or his mother should die, he must immediately resign his employment, to fulfil the duties which a son owes to his parents, and which cease not with life; and, at all events, he is removed at the end of three years. No two relations within the fourth degree can sit together at the same board. In each of the six boards which sit in Pekin there is a censor, who has no deliberative voice, but listens to their discussions, makes his remarks, and, like our speaker in the House of Commons, keeps them in order, refers to precedents, and the like. He is supposed to be the confidential servant of the sovereign, whom he informs of what is going on, and what are the sentiments of the several members. These six censors may be considered as imperial spies, and they form an extraordinary board called *Too-tche-yuen*, whose chief business is that of dispatching their visitors or sub-censors to all parts of the empire, to examine into and report upon the conduct of the several officers, and to discover whether any and what abuses are alleged against them; and, to complete the system of espionage, persons are invited to send up informations against the officers of government, all of which are registered in this extraordinary tribunal.

In this precarious situation, a magistrate may consider himself fortunate if he escapes the shafts of private malice, or retires from office without having incurred disgrace, or some more serious punishment, for the commission of some fault, or the dereliction of some duty; for, where the offices of state are open to the lowest of the people, when possessed of the requisite qualifications, the candidates for employment become so numerous, that every trifling fault is laid hold of to create a vacancy; and these frequent removals and degradations fall in precisely with the system of the government, which is to break down all connection between the officers and the people, and to turn the respect and veneration of the latter exclusively to the sovereign. On the same principle, it is supposed that the extortions and malversations of officers high in the government are frequently winked at, until, at a proper season, the hand of power lays hold of the treasure corruptly obtained, and gets rid, in a legal manner, of the whole family of the delinquent. It is true, a magistrate in China is tried by his brother magistrates; but when the sovereign is the accuser, as is generally the case where an officer of state is the accused, the result is pretty certain. The favourite and principal adviser of the late Kien-lung was brought to trial by his imperial master, Kia-king, on charges of the most frivolous nature, as that of having walked through the middle gate, which is alone reserved for the emperor, having a pearl in his possession larger than any belonging to the imperial family, &c.; but the object was answered; he was condemned to death, his whole property, which was immense, confiscated, and all his relations dismissed from their employments, and banished into Tartary. We may form a tolerably correct opinion of the manner in which the criminal courts administer justice in cases wherein the emperor is personally concerned, from the trials that took place in consequence of the attempt that was made to assassinate the late Emperor Kia-king. He announces to the public a revolt, takes blame to himself, abuses his ministers for their negligence, to which he ascribes his misfortune, and ends his proclamation in a strain of self-reproach and great hypocritical humility. As the greater part of the handful of rebels who attempted to storm the palace were killed in the act, and the rest that were taken put to death, some by beheading, others by a slow and lingering process, some hacked and mutilated in the public market-place, and others "cut into ten thousand pieces," it might be supposed that here the business ended. No such thing. The emperor, in his proclamation, denounces a particular sect, which once caused a revolt in four provinces, that took eight years to subdue; hence the country magistrates, to make amends for the carelessness of the ministers, persecuted all sects, and, among others, the Christians. One of the magistrates had the courage to send to the capital a spirited remonstrance, in which he stated that many innocent persons had been brought to trial, tortured, and suffered death; that numbers were unjustly confined, or passed from court to court, after being put to the torture under pretence of preparation for trial; and that they were finally liberated, without trial, after their health was destroyed and their property wasted. The whole document exhibits a melancholy picture of abuses in the administration of the criminal jurisprudence of this supposed virtuous and humane nation.

The administration of the government is conducted by six departments, to each of which there is a president and a certain number of members, forming so many boards, similar to those of our admiralty and treasury boards; and the six presidents form a distinct board of themselves,

China.

which, with certain princes of the blood, may be called the extraordinary council of the state. Each board sends out its appropriate officers to every part of the empire, with and from whom it has to correspond and receive reports; abstracts of which, and of all its proceedings, are daily laid before the emperor by one of the *co-laos* or presidents, whom he generally selects as his favourite and confidential minister and adviser. The respective duties of these boards are so interwoven with the laws of the empire, that a brief view of the laws will best explain the nature of the executive governments. (Grozier and Du Halde's *Hist. of China; Mém. sur les Chinois;* Macartney's *Journal;* Staunton's *Authentic Account of an Embassy,* &c.; Barrow's *Travels in China.*)

Laws.

When Pauw observed that China was governed by the whip and the bamboo, he was not aware of the theoretical application of these instruments, especially the latter, to the whole code of civil and criminal law. The remark was not meant to extend beyond the practical application of these machines to the human body, which, it must be owned, are effectual aids towards the establishment of a strict police, and that they are freely enough administered in keeping the peace among the lower orders; but their use in this way is by no means so extensive as is generally supposed, and as the letter of the law would seem to imply. This great empire may, notwithstanding, be aptly enough compared to a great school, of which the magistrates are the masters, and the people the scholars. The bamboo is the ferula, and care is taken that the child shall not be spoiled by sparing the rod. The bamboo, however, is not used merely for flogging the people. In the fundamental laws of the empire it forms the scale by which all punishments are supposed to be proportioned to the crimes committed, and which are carefully dealt out by weight and measure; and here also we recognize the work of an ancient people in a rude state of society. In a small family, or a community consisting of a certain number of families, it may just be possible to "adapt the penalties of the laws in a just proportion to the crimes against which they are denounced;" but the continuance of such a system in an overgrown commonwealth affords no proof of refined or extensive notions of jurisprudence. Punishment, as an example to deter others from the commission of crimes, would seem, indeed, to be less the object of Chinese legislation than that of satisfying the claims of rigid justice: to wipe off a certain degree of crime by the infliction of a proportionate degree of suffering.

The code of laws called the *Leu-lee* has undergone several changes by different dynasties, but the principle of the laws has remained the same. This book is to China what Burns's *Justice* is in England, and is familiar to all who have any pretensions to literature. "The magistrates and the people," says the Emperor Sun-chee, "look up with awe and submission to the justice of these institutions." An European will regard them with different feelings. The frequency and the severity of corporal punishments, if literally inflicted, would be shocking and disgusting; but, as Sir G. Staunton has observed, "there are so many grounds of mitigation, so many exceptions in favour of particular classes, and in consideration of peculiar circumstances, that the penal system, in fact, almost entirely abandons that part of its outward and apparent character" The same observation will apply to the penalty of death, which appears to be affixed to crimes of even a comparatively slight nature; for if we are to judge from the very small number of criminals that are said to be executed annually, capital punishments must be rarely inflicted. According to the *Pekin Gazette,* the number of criminals executed in 1828 was only 789. This, however, may in some measure be explained by the fact, that, while in ordinary cases the executions are postponed until the autumnal assize, when the emperor revises and confirms the sentences of the provincial governors, in such as robbery with murder, highway robbery, piracy, rape, &c., executions may take place immediately, without being referred to the emperor, and these in all probability never find their way into the *Gazette.*"

The number of blows to be inflicted with the bamboo may not only be considered as the measure or scale of crimes, but as regulating also the mode or practice of punishment. The letter of the law, severe as it may appear to be in denunciation, is more lenient in execution. Thus, ten blows of nominal punishment are practically reduced to four, and 100 to 40; and, in many cases, these blows are redeemable by fine.

This bamboo, that makes so conspicuous a figure in the Chinese code, is limited by law to two sizes; the larger 5 feet 8 inches in length, $2\frac{2}{4}$ inches broad, and 2 inches thick, weighing $2\frac{2}{5}$ pounds; the smaller the same length, 2 inches broad, and $1\frac{1}{3}$ thick, weight about $1\frac{5}{6}$ pound.

The cangue, or more properly the *kia,* is a wooden collar for the neck, 3 feet long, 2 feet 9 inches broad, weighing, in ordinary cases, 33 pounds.

The iron chain, by which all criminals are confined, is 7 feet long, weighing $6\frac{2}{3}$ pounds; besides which they use wooden handcuffs and iron fetters.

Various kinds of torture of the hands, feet, ancles, &c. are made use of to extort evidence or confession; but it is not permitted to put the question by torture to those who belong to any of the eight privileged classes, in consideration of the respect due to their character; nor to those who have attained their seventieth year, in consideration of their advanced age; nor to those who have not exceeded their fifteenth year, out of indulgence to their tender youth; nor, lastly, to those who labour under any permanent disease or infirmity, out of commiseration for their situation and sufferings. The eight privileged orders spring out of, 1. imperial blood and connections; 2. long service; 3. illustrious actions; 4. extraordinary wisdom; 5. great abilities; 6. zeal and assiduity; 7. nobility of the first, second, and third rank; 8. birth; all of which, excepting the first, seventh, and eighth, have not, in fact, any existence. Their chief privilege consists in not being liable to be tried for any offence, without a specification of the crime being laid before the emperor, and his express commands issued for that purpose.

There are five degrees of punishment.

The first degree is a moderate correction inflicted with the lesser bamboo, "in order that the transgressor of the law may entertain a sense of shame for his past, and receive a salutary admonition with respect to his future conduct." This correction extends from ten to fifty blows; the first, in practice, reduced to four by the emperor's grace; the last never exceeds twenty blows.

The second class of punishments extends from sixty to a hundred blows, of which from twenty to forty are actually inflicted.

The third division is that of temporary banishment to any distance not exceeding 500 *lee* (about 150 miles), "with the view of affording opportunity of repentance and amendment;" and it extends from one to three years' banishment.

The fourth degree of punishment is that of perpetual banishment, which is reserved for the more considerable offences, and extends to the distance of 2000, and even 3000 *lee,* with 100 blows of the bamboo.

The fifth and ultimate punishment which the laws ordain is death, either by strangulation or decollation.

At the head of the code are placed ten offences of a *treasonable nature:*—1. *Rebellion,* defined an attempt to violate the divine order of things on earth; 2. *Disloyalty,*

an attempt to destroy the imperial palaces, temples, or tombs; 3. *Desertion* to a foreign power; 4. *Parricide*, or the murder of parents, uncle, aunt, grandfather, or grandmother; 5. *Massacre*, or the murder of three or more persons in one family; 6. *Sacrilege*, or stealing from the temples any sacred article, or any thing in the immediate use of the sovereign; 7. *Impiety*, or negligence and disrespect of parents; 8. *Discord in families*, or a breach of the legal or natural ties, founded on connections by blood or marriage; 9. *Insurrection* against the magistrates; 10. *Incest*, or cohabitation of persons related in any of the degrees to which marriage is prohibited. And these crimes are stated to be placed at the head of the code, from their being of so heinous a kind, that, when the offence is capital, it is exempted from the benefit of any act of general pardon, and that the people may learn to dread and avoid them.

Offences committed by officers of government, which, in ordinary cases, are punishable by the bamboo, are commutable for fine or degradation, according to the number of blows to which they are nominally liable. Thus, if publicly offending, instead of sixty blows, they forfeit a year's salary; and instead of a hundred, lose four degrees of rank, and are removed from their situation. If the offence be of a private nature, the punishment is doubled. The only male descendant of parents or grand-parents, who are aged and infirm men, if his age exceeds seventy, and youths under sixteen, are entitled to the indulgence of commuting the punishment awarded by law. Women, too, may have the sentence of banishment remitted, on payment of a fine; and when convicted of offences punishable with the bamboo, "they are permitted to retain a single upper garment while the punishment is inflicted, except in cases of adultery, when they shall be allowed the lower garment only."

The following table exhibits a scale of pecuniary redemption, in cases not legally excluded from the benefit of general acts of grace and pardon. They are not necessarily redeemable; but, by edict of Kien-lung, may be made so upon petition.

Rank of the Party offending.	Sentence.	Pecuniary Commutation.
		Oz. of Silv.
An officer above the 4th rank	Death by strangulation or decollation.	12,000
——— of the 4th rank......		5000
——— of the 5th or 6th rank		4000
——— of the 7th or any inferior rank, or a doctor of literature..........................		2500
A graduate or licentiate.........		2000
A private individual.............		1200
An officer above the 4th rank	Perpetual banishment.	7200
——— of the 4th rank......		3000
——— of the 5th or 6th rank		2400
——— of the 7th or any inferior rank, or a doctor of literature..........................		1500
A graduate or licentiate........		1200
A private individual.............		720
An officer above the 4th rank	Temporary banishment, or blows with the bamboo.	4800
——— of the 4th rank......		2000
——— of the 5th or 6th rank		1600
——— of the 7th or any inferior rank, or a doctor of literature..........................		1000
A graduate or licentiate........		800
A private individual.............		480

There is every reason to believe that these pecuniary commutations of banishments bring considerable sums into the treasury.

The *Ta-tsing-leu-lee* embraces an epitome of the whole system of government, and of civil and criminal jurisprudence. Besides the introductory part, which contains a general view of the laws, the code consists of six principal divisions, corresponding with the six supreme boards or departments by which the general administration of the empire is conducted. Thus, the *first division* of the code relates to that part of the *civil law* which falls under the cognizance of the *Lee-pou*, or the department which examines candidates for employment, and nominates to appointments, subject to the approbation of the emperor. This division consists of two chapters; the first defining the duties and regulating the offices of the several magistrates, the rule of hereditary succession, and the penalties attached to malversation. The second book relates chiefly to the conduct of the provincial magistrates. The capital offences classed under this division are, great officers of state presuming to confer appointments by their own authority, and without the sanction of the emperor; undue solicitation of hereditary honours; all cabals and state intrigues among the officers of government; collusion between the provincial magistrates and the officers of the court; addressing the emperor in favour of any great officer of state, which is construed into a treasonable combination, subversive of legitimate government; destroying edicts or seals of office; all of which, however, fall within the class of redeemable punishments, which are not excluded from any general act of grace or pardon.

The *second division* of the code relates to the *fiscal laws*, which are placed under the cognizance of the *Hoo-pou*, or financial department. They are various, and relate, 1. To the enrolment of the people, personal service, levying of taxes, punishment of persons deserting their families, care of the aged and infirm. 2. The law of holding, mortgaging, selling, &c. lands and tenements. 3. Regulations respecting marriages and divorces. 4. Respecting public property, the coinage, the revenue, the public stores. 5. Duties and customs, smuggling, false manifests, &c. 6. Private property, the law of usury, of trusts, &c. 7. The regulations concerning sales and markets; monopolizing and fraudulent traders; false weights, measures, and scales; manufactures not conformable to the fixed standard, &c. The section concerning marriages and divorces is brought under this division of the code for no other reason, it would seem, than to regulate the descent and distribution of property. The law allows seven justifiable causes of divorce: 1. Barrenness; 2. lasciviousness; 3. neglect of her husband's parents; 4. talkativeness; 5. thievish propensities; 6. envious and jealous temper; 7. inveterate infirmity. But, in spite of any or all these causes, a wife cannot be divorced if she can plead any of the three cases: 1. having mourned three years for her husband's parents; 2. her husband having become rich since the time of her marriage; 3. the wife having no parents living to receive her.

The *Le-pou*, or board of rites and ceremonies, takes cognizance of all offences committed under the *third division* of the code, which is subdivided into two sections, and relates, 1. To the *sacred rites*; the administration of the prescribed ritual; the care of altars, sacred terraces, and the tombs; unlicensed forms of worship; magicians; leaders of sects; and teachers of false doctrines. 2. To miscellaneous observances respecting the palaces, the emperor, his equipage, and furniture; to the public festivals and days of ceremony; sumptuary laws relative to dress and habitations; celestial observations and appearances; regulations for funerals and country festivals.

The *fourth division* contains the laws by which the military are governed, the direction and superintendence of which are placed under the department of state called the *Ping-pou*. It consists of five sections. The first relates to the protection of the palace, and of course to the person of the emperor; the duties of the imperial guards; examination of passports, &c. The second is entitled the *government of the army*, and may be considered as the mutiny act, or articles of war, of China. Every neglect of duty, disobedience of orders, and want of discipline; fraud, embezzlement, desertion, are punished with extreme severity; and many of the offences herein specified are capital. The third section relates to the *protection of the frontier*, a most important consideration with this suspicious government; the fourth prescribes regulations respecting the horses and cattle belonging to the army; the fifth for the expresses and government posts, the post-horses, messengers, and horses employed in the conveyance of dispatches.

The *fifth division* contains the code of criminal law administered by the *Hing-pou* or criminal tribunal, which supplies the judges or assessors to all the other departments. It consists of eleven sections. The first, entitled *robbery and theft*, awards punishments for every species of robbery or theft that could well be devised; extorting property by threats; obtaining it under false pretences; kidnapping and selling free persons as slaves; disturbing graves, &c. The second relates to *homicide*, and may be considered as a most singular, if not successful, attempt to discriminate the exact proportion of guilt, for the same offence, in different persons, or different degrees of offence in the same person, according to the situation and circumstances of the offending parties. In every case of preconcerted homicide, the original contriver is condemned to die by decapitation, the accessaries by strangulation; accessaries to the intention, but not to the fact, are punishable with one hundred blows and perpetual banishment. Those who murder, with intent to rob, are beheaded, without distinction between principals and accessaries. Parricide subjects all parties to suffer death by a slow and painful execution; the attempt to commit parricide is death by decapitation. Slaves attempting to murder, or actually murdering their masters, are liable to the same punishment. A husband may kill his wife if caught in the act of adultery, and also her paramour; and a thief may be put to death if taken in the act of robbing a house; but, in either case, it would be murder if put to death after being seized. The preparing of poisons, and rearing of venomous animals, are capital offences. Practitioners of physic, or barbers (for they have no surgeons), who puncture with the needle, giving drugs, or performing operations contrary to the established rules and practice, and thereby killing the patient, are guilty of homicide; but, if proved to have been merely an error in judgment, the offence is redeemable by fine, but the doctor and the barber must quit their professions for ever; if the medicines, however, were given intentionally to kill or injure the patient, the practitioner must suffer death by decapitation. All persons guilty of killing in an affray, though without any express or implied design to kill, whether the blow be given with the hand or the foot, with a metal weapon or instrument of any kind, shall suffer death by strangulation. There is a clause, however, by which any person killing another in play, by error, or purely by accident, may be permitted to redeem himself from the punishment of killing or wounding in an affray, by the payment of a fine to the family of the deceased person; but the case of *pure accident* is very carefully defined and exemplified. It must be one "of which no sufficient previous warning could be given, either directly, by the perception of sight and hearing, or indirectly, by the inferences drawn from judgment and reflection."

In the third section, entitled "quarrelling and fighting," there is a minute and circumstantial detail of blows given under every conceivable case and situation, and in every possible relation in which the parties could stand towards each other. It fixes the periods of responsibility for the consequences of a wound; it awards the penalty of death on a slave who shall strike his master; on a son who shall strike his father or mother; on a grandson who shall strike his paternal grandfather or grandmother; on a wife who shall strike her husband's father, mother, paternal grandfather or grandmother; but if a father, mother, paternal grandfather, or grandmother, shall chastise a disobedient child or grandchild in a severe and uncustomary manner, so that he or she dies, the party so offending shall be punished only with one hundred blows, which, in reality, are no more than forty; and when any of the aforesaid relations are guilty of killing such disobedient child or grandchild designedly, the punishment shall be extended to sixty blows and one year's banishment. A parent may at any time sell his children to any one except strolling players and professors of the magic art. This distinction which the law makes between the parent and child, and the almost unlimited authority which is given to the former over the latter, would lead one to conclude, that, if the crime of infanticide be not sanctioned, it is at least connived at, by the government. There is every reason, however, to believe that the extent of it has been grossly exaggerated, and that the greater part of infants taken up in the streets of large cities by the police have died in the birth, and been laid out to avoid the expense of burial; or been exposed alive, with the view of their being taken care of as adopted children, or conveyed to hospitals for the reception of deserted children.

In the cases above stated, the child murdered is supposed to have been *disobedient*, which is a crime of the deepest dye, as affecting the principle on which the whole system of government is founded; and, from section 294, it is evident that killing a son, grandson, or slave, under any circumstances, with the aggravation of imputing his death to an innocent person, is not a capital offence. "Whoever is guilty of killing his son, his grandson, or his slave, and attributing the crime to another person, shall be punished with seventy blows, and one and a half year's banishment." But "a child or grandchild who is guilty of addressing *abusive language* to his or her father or mother, paternal grandfather or grandmother; a wife who is guilty of addressing abusive language to her husband's father or mother, paternal grandfather or grandmother, shall, in every case, suffer death, by being strangled." They must, however, themselves complain, and themselves have heard the abusive language. In like manner, a slave is liable to capital punishment for addressing abusive language to his master.

The fifth book relates to indictments and informations of all kinds; the sixth to cases of bribery and corruption, and seems to contain provisions against bribery in almost every shape which it can be supposed to assume. It is not easy, however, to reconcile these apparent appropriate provisions with that systematic corruption which, under the less odious name of presents, is prevalent in every department of the administration of public affairs and public justice in China. There is a scale of punishment for the value of the bribe received, from one ounce of silver to 120 and upwards; the first entailing sixty blows, the last death by strangulation, when the object is in itself lawful; but, if unlawful, an ounce of silver incurs seventy blows; and eighty ounces and upwards, death by strangulation. That they all take bribes is well known; yet it

appears by a note in the original (*Leu-lee*), that, in the thirty-third year of Kien-lung, a governor of a city in the province of the capital was tried, and sentenced to suffer death, for taking a bribe of 7000 ounces of silver to stop proceedings in a case of disorderly conduct and contempt of court; though, finding himself unable to accomplish the object, he had returned the money. In like manner, there are so many provisions against extortions and corrupt practices on the part of great officers of state and their families, that it might be supposed no such practices could exist. The last section of this book is curious, as affording a proof of the care with which the imperial prerogative is fenced round. " All military officers of government, whether stationed at court or in the provinces, are prohibited from receiving presents of gold, silver, silk-stuffs, clothes, wages, or board-wages, from individuals in any of the three principal ranks of hereditary nobility" (mostly related to the royal family and other Tartar chieftains). Any breach of this law deprives them of their rank and employment, and renders them, moreover, liable to the punishment of one hundred blows, and remote perpetual banishment. The second offence of this kind is capital.

The seventh book awards punishment for frauds and forgeries, falsification of the imperial seal or imperial almanac, counterfeiting the current coin of the realm, seducing persons to transgress the laws, &c. The eighth is entitled incest and adultery. Criminal intercourse with an unmarried woman, though by mutual consent, is punishable with seventy blows; with a married woman eighty blows; deliberate intrigue with either, with one hundred blows; a rape with death by strangulation; and criminal intercourse with a girl under twelve years of age is punishable as a rape. Adultery with the wife of any civil or military officer is death; but civil or military officers committing adultery with the wife of a private individual is degradation, one hundred blows, and wearing the cangue for a month. In all ordinary cases of adultery among the people, the punishment is one hundred blows, and the cangue for a month. An unnatural crime forcibly committed, or committed on boys, is punishable as a rape; but by mutual consent the parties are punishable only with one hundred blows, and the cangue for a month. In all cases of criminal intercourse, the law is more severe towards the woman than the man, and towards slaves than freemen. " All civil or military officers of government, and the sons of those who possess hereditary rank, who shall frequent the company of prostitutes and actresses, shall be punished with sixty blows;" which is, in fact, no punishment at all, as the blows, in reality, are reduced to twenty, and redeemable for a mere nominal sum, not exceeding two or three shillings.

The ninth book is entitled miscellaneous offences, among which is that of gaming; any person convicted of which is punishable with eighty blows. Yet in every street and corner, and in the very temples, the lowest of the people may be seen daily, and every hour of the day, playing at cards, dice, or a sort of game resembling chess. Accidental incendiaries are flogged and fined, according to the consequences of the fire they have occasioned; and wilful incendiaries are punished with death, provided it be proved that the fire was occasioned with a view of plunder. Stage-players and musicians are prohibited from representing emperors, empresses, famous princes, ministers, and generals of former ages, on pain of receiving one hundred blows for every breach of this law. Yet, as these are the favourite and most usual exhibitions, it may be presumed that this law is obsolete. There is, indeed, a saving clause, which says that, " by this law, it is not intended to prohibit the exhibition on the stage of fictitious characters of just and upright men, of chaste wives, and pious and obedient children; all which may tend to dispose the minds of the spectators to the practice of virtue."

The tenth and eleventh sections contain regulations with regard to arrests and escapes, imprisonment, judgment, and execution.

The *sixth* and *last division* contains the laws and regulations respecting the public works, which are placed under the superintendence of the department of state called the *Cong-poo*, or board of public works. It has only two sections; the first relating to public buildings, and the second to the public roads. From the first it appears, that this board has also the superintendence of the public manufactures of the state, such as military weapons, silks, stuffs, porcelain, &c.; and that if any private individual be convicted of manufacturing for sale, silks, satins, gauzes, or other stuffs of this nature, according to the prohibited pattern of the *lung* (dragon), or the *fung-whang* (phœnix), he shall incur the penalty of one hundred blows, and the goods so manufactured be forfeited to the state. This book, and the next, concerning the keeping in repair of the public roads, embankments, and bridges, contain a number of regulations and petty penalties for neglect and malversation, that are beneath the dignity of legislation, and fitted rather for the subjects of deliberation in a parish vestry. Indeed, the whole body of Chinese law, civil and criminal, consists of such minute meddling with all the common concerns of life as to be utterly unfit for any practical application, except to such mere machines as the Chinese are, for whom it seems to be admirably suited to answer the intended purpose. Nothing can more clearly exhibit this great multitude of human beings as an inert and sluggish mass, without a heart, and without one single idea of the liberty and independence of the human mind, than the minute and paltry regulations under which it has voluntarily submitted to be bound and shackled for so many thousand years.

After all, there is reason to suspect that this minute measuring out of punishments by a scale, in order to adapt them to their respective degrees of criminality, is pregnant with the most gross injustice; and that, where so much pains are ostentatiously displayed to deal out justice by weight and measure, there is so much less of it in the execution. Many examples might be cited in confirmation of this opinion, but a few will suffice. In the eleventh volume of the *Chinese Memoirs*, Père Amiot gives a curious account of a master mason that died by an accidental blow of the bamboo, while under a flogging by order of an officer of the household of a prince of the blood, whose house he was rebuilding in Pekin. As culpable homicide is death by the law of China, the officer bribed one of the mason's labourers, for ten ounces of silver, and the promise of a respite, to take the blame on himself, as the consequence of a quarrel; and, for three ounces of silver, two or three of the labourers were to give evidence to that effect. The man was tried, and condemned to suffer death on the day of general execution in autumn. On the morning of that day, or the evening preceding, it is the custom, it seems, to bring up all the prisoners under sentence of death to be interrogated by the *co-laos*, or principal ministers of the crown; and, on this occasion, the heart of the bricklayer's labourer failing him, he discovered the whole transaction. The offending officer was immediately tried; and, coupling his original offence with the aggravated one of exposing an innocent person to suffer death, was sentenced to die by a slow and painful execution. Nor was this all; the judges and assessors of the court, who had originally tried the offence, were each degraded one rank, and mulcted of their salary and emoluments. This is given by Père Amiot as an instance of Chinese justice;

China.

but it tells as strongly the other way; for, if such gross iniquity, committed in open day, and in the presence of a multitude, was thus connived at at the very fountain-head, what may not be expected at a distance, where the stream is still more muddy? That government can have no high notions of justice or morality which winks at, and sometimes encourages, a criminal to find a substitute, even when the punishment accorded to the crime is death. There is much truth, as many can testify, in the severe remark of Pauw—" Le juge veut faire une exécution, et il lui faut un patient; or il prend celui qui se présente." In the case of an English seaman, tried for the murder of a Chinese, when they failed in their endeavours to procure a black slave, or a criminal of Macao, or a sick person on the point of death, to execute,—not to satisfy justice, for it was an accidental death in a scuffle, but to satisfy the criminal court of Pekin, to which they had unluckily for themselves appealed; they had recourse to one of the meanest and most paltry expedients that ever disgraced a civilized government. " All the proceedings," says Sir G. Staunton, " were founded on a story fabricated for the purpose,—a story in which the Europeans did not concur, though asserted to have done so; which, in fact, the Chinese magistrates themselves, or the merchants under their influence, invented,—which the Chinese witnesses, knowing to be false, adopted,—and which, lastly, the sovereign himself appears to have acquiesced in without examination." Under such a government, the laws are either a dead letter, or may be so perverted that, under their sanction, the innocent may be made to suffer, and the guilty escape punishment.

In addition to all this, that horrible system of visiting the crimes of the guilty upon the heads of the innocent, which pervades all the despotic governments of the East, is also practised in China, in all cases of rebellion and treason; though it is not carried so far as among the Hindus, who, not content with cutting off a whole family, swept away whole towns and villages in which treason had appeared, as a terrible example to prevent other villages from harbouring traitors. Such are the dreadful effects of despotism, and the miseries inflicted on innocent families, where the people have no voice in the government; such a government is always more ready to punish than to protect. (*Ta-tsing-leu-lee*, translated by Sir G. Staunton.)

Prisons.

The condemned criminals for ordinary offences are kept in prison till autumn, when they are all executed in every part of the empire on a particular day. In general, the prisons are described as spacious, neat, and clean. Navarette, who was himself confined in one of them, says that they have large airy courts for the prisoners in the daytime; that overseers are always present to quell any noise or disturbance; and that they contain temples for the priests to resort to. The priests, he says, make a harvest in the prisons, as those whose trials were pending were constantly consulting the priests as to the issue, and they became the more religious the nearer the day of trial approached. Criminals are kept in chains, and always apart; so are the women kept separate from the men; and the missionary observed so little gallantry on the part of the men, that though there were gratings in the doors of the women's cells, the Chinese never once visited them. A very different picture, however, is given of the state of the prisons, and the prostitution of the females confined in them, in the province of Canton, from better authority than Navarette,—an official report to the emperor on the state of the prisons. The scenes of depravity herein exhibited are horrible beyond description.—(*MS. Report.*)

The durability of a system so arbitrary, and an administration so corrupt, is not a little owing to the incessant and indefatigable vigilance of the police; to the absence of all political meetings or societies, and of all discussions respecting public measures; to the gradation of obedience throughout every class of society, inculcated by precept, by example, and by the bamboo; and certainly not a little to that spirit of national industry, which is the grand preserver of national tranquillity.

Revenue.

It is almost impossible to arrive at even an approximation to the amount of the public revenue and expenditure of the Chinese empire. A large proportion of the taxes is paid in grain, silk, and other products, the market value of which varies from year to year. Each province is required not only to support itself, but to furnish annually a certain amount for the support of the emperor and his court. Some of the provinces, however, fail in raising enough even for their own outlay; and it is well known that his majesty is continually embarrassed for want of funds. The amounts given, by various authors at different times, of the revenue of China are so discordant, that little reliance can be placed upon them. In 1587 Trigault, a French missionary, stated it at 20,000,000 taels, or about L.6,600,000 sterling; in 1655 Nieuhoff estimated it at 108,000,000 taels, about L.36,000,000. Twelve years later, Magelhaens reckoned it at about L.4,000,000. Towards the close of the eighteenth century it was given by Sir George Staunton at L.66,000,000, of which sum, however, little more than a fifth was transmitted to Pekin. Dr Medhurst, on the authority of original sources, gives the revenue as follows:—

Sent to Pekin.				
Land-tax in money.........taels	31,745,966	=	L.10,581,955
Land-tax in grain.............shih	4,230,957	=	4,230,957
Customs paid in money.......taels	1,480,997	=	493,666
Kept in Provinces.			
Land-tax in money...........taels	28,705,125	=	9,568,375
Grain ....shih	31,596,569	=	31,596,569
Total		..	L 56,471,522

From this it will be seen, that in proportion to the population the taxes are very light, amounting only to about 3s. $3\frac{1}{2}$d. per head; and if we reckon only that which is sent to Pekin, namely, L.15,206,378, it will not amount to much more than 10d. per head. The principal source of revenue is the land-tax, which is a very light impost, amounting not, as some suppose, to one-tenth, but, according to Medhurst, more usually to one-fiftieth or one-hundredth of the produce. There are also taxes on pledged articles, and more particularly a heavy impost on salt. In a country like China, which has few or no resources beyond itself, a limited foreign commerce, and few manufactures; where the consumers are fully equal to the capabilities of the soil, and where every production is hastily devoured by a needy population; there is little left for a government to glean, or, to use a Chinese phrase, to squeeze out of the already exhausted pockets of the people. The long peaceful state of the country is, no doubt, in some measure to be attributed to the people being lightly taxed. The extraordinary sources of revenue that are resorted to in times of war or bad harvests are,—sale of offices and honours, temporary increase of duties, and demands for contributions from wealthy merchants and landholders. The first is that most generally resorted to, and is naturally that most agreeable to the great body of the people. The mines of gold and silver, pearl fisheries in Manchooria and elsewhere, and such like sources, furnish an important addition to the imperial revenue. The expenditure almost every year exceeds the revenue, but how the deficiency is made up is not very clear. In 1832 the emperor stated, that the excess of disbursements was 28,000,000 taels (L.9,300,000); and in 1836 it was still greater, and offices and titles to the amount of 10,000,000 taels (L.3,300,000) were put up for sale to supply it.

Religion.

There are three religious systems in China,—the state religion, at the head of which is the emperor, and those of

Tao-tse and Buddha. In the state religion the emperor is believed to be the sole vicegerent of the Supreme Being upon earth. He is the only individual that can stand between Heaven and the people, having the same relation to the former that the latter are supposed to bear to him. The people have no sabbatical institution, no congregational worship, no external forms of devotion, of petition, or thanksgiving, to the Supreme Being. The emperor being high priest performs the sacred duties according to the ancient ritual, and at certain fixed periods. Religion, as a system of Divine worship, as piety towards God, and as holding forth future rewards and punishments, can hardly be said to exist among the people. The emperor alone officiates at all the solemn ceremonies for propitiating Heaven or expressing a grateful sense of its benefits; and as "sacrifices and oblations can only be acceptable to Heaven when offered up with humble reverence, and a pure and upright heart," he prepares himself for such occasions by fasting and abstinence, and acts of benevolence and mercy to his subjects.

The equinoxes are the periods when the grand sacrifices in the temple dedicated to Heaven, within the precincts of the palace, are offered up; and every kind of business in the capital, all feasts, amusements, marriages, funerals, must be suspended during the ceremony, the moment of which is announced to the people by the tolling of the great bell in Pekin.

A ridiculous dispute was carried on with great vehemence between the Jesuits and other sectaries of the Catholic religion, whether the emperor did not offer his sacrifices and oblations to *Tien* as the visible and material heaven, and whether the Chinese were not atheists, at the head of whom he was the officiating high priest. There is not an expression in their ancient book of rites that warrants such a supposition. The *Lee-kee* describes the *Tien* as having neither voice, nor smell, nor figure, substance, nor dimentions; it gives him the attributes of omnipotence, omniscience, and ubiquity, and considers him as rewarding the good and punishing the bad; that public calamities are the instruments he employs to excite in the sovereign, and through him in the people, a reformation of morals. The names by which the sovereign power is known in their writings are,—*Whang-tien*, the illustrious heaven; *Chang-tee* the Supreme Ruler; *Tien-tee*, heaven and earth; *Che-chung*, the first and the last (Alpha and Omega); *Ken-puen*, root and branch.

All ranks, however, from the emperor downwards, are full of absurd superstitions. The imagination of untutored man, not easily comprehending a power so almighty and universal, created a number of inferior spiritual beings as the harbingers and agents of his will; and these spiritual agents, which the Chinese call *Quei-shin*, are invisible attenuated beings, some white and good, the advocates of men, others black and wicked, the punishers of sin; and these "illustrious subjects of the Great Ruler" are supposed to preside over the five seasons of the year, over mountains and rivers, over the hearth and the door of the house, and influence all the concerns of men. To these spirits certain duties are prescribed, and certain oblations offered; the men usually bring wine, the women tea; but these are private ceremonies and heartless duties; the devotion of religion is totally wanting; and in such a state it is not surprising that the doctrines and the practices of the sects of Tao-tse and of Fo should captivate the vulgar, and seduce them to a religion that spoke more strongly to the senses. It would seem, indeed, that the establishment of some popular religion is unavoidable, and that of Fo may, on this ground, be encouraged by the government, though it derives little or no support from it. The ancient religion of China entertained the idea of spiritual beings; but they never clothed them in a corporeal form. In the time of Confucius their temples were without images; their guardian gods and their evil genii were mere imaginary beings, to which they neither gave form nor substance; but when the priests of Fo found their entrance into China, they brought with them all the follies and absurdities of the doctrine of Buddh, and grafted them on the superstitions of the Chinese. They filled their temples with all manner of images, each having its peculiar virtues and peculiar influences, and levied for each a tax on the credulity of the people. In some of these temples are not fewer than three hundred sainted personages,—monstrous figures, as large as, and frequently many times larger than, human beings. Their bells and their beads, and burning of incense and tapers,—their images and their altars,—their singing and processions, were well calculated to seduce the populace, who had no outward forms of any religion. So strong was the resemblance of the interior of a temple of Fo, the dress of the priests, and the ceremonies of devotion, to those of the church of Rome, that one of the Catholic missionaries says, it seemed as if the devil had run a race with the Jesuits to China, and having got the start of them, had contrived these things for their mortification.

The Tao-tse are of Chinese origin, and sprung up under the very nose of Confucius, about 500 years before Christ. Their tenets resemble those of Epicurus; they pretend to magic and alchemy, to consult oracles, and to deal with demons; and they keep old women, who are regarded as a kind of witches. The priests of Fo came from Upper India into China, by invitation from a weak emperor, between the 60th and 70th year of the Christian era. Their tenets resemble the Pythagorean. They kill no living animal, and eat no animal food, lest they might partake of a relation or friend, whose soul had taken up its abode in the animal; and they believe that the human soul, in its transmigration through an infinity of corporeal existences, becomes purified and perfect, and at length is reunited to the Deity, from whom it originally emanated. They consider the consummation of felicity to consist in the annihilation or total suspension of every faculty of the soul, leaving a void for that of Fo to occupy. Arrived at this stage, the devotee soon dies from exhaustion and want of food; his body is burnt, the ashes put into eight urns, upon which a tower of nine roofs and eight apartments is built, and an urn placed in each apartment; and this is said to have been the origin of the numerous tall pagodas that appear in every part of China. It is pure Shamanism, which may be traced from the Caspian Sea to Japan; from the Saghalien Oula to the Persian Gulf. The priests profess the most sublime notions of virtue, and many of them are said to practise the most refined piety; prayers, fastings, austere and rigorous punishments for the sins of others; chastity, abstinence, penitence, contempt of bodily suffering, to secure for the indestructible soul a better abode in the circle of its transmigrations.

Some of the Catholic missionaries, however, have represented the priests of Fo as living in all manner of vice and luxury; but the testimony of unprejudiced travellers is against them, and even several of the Jesuits speak highly in their favour, saying that, in their moral doctrines, there is little to reprehend; that they inculcate benevolence, humility, reciprocal kindness, command over the passions, and tenderness towards the brute part of the creation. But it may be questioned whether the priests of Fo or Tao-tse act upon any fixed principles. Some of them, for instance, refuse to drink wine, others to eat garlic and onions; some practise celibacy, and profess perpetual continence; others have several wives and concubines. It is quite certain that neither of them are much

respected by the government. Their protection or persecution depends on the caprice or feeling of the ruling sovereign. At one time we find their temples demolished, the materials employed for the public buildings, the bells and brazen statues melted down into money, and the priest, by an imperial edict, reduced to the rank of the people. One emperor persecutes the Ho-chang of Fo, and encourages the Tao-tse. He drinks the beverage of immortality, and dies soon after; his successor eradicates the Tao-tse for poisoning the sovereign, and sanctions the worship of Fo. At present the number of temples dedicated to Fo, and of the priests attached to them, is incalculable. They not only occur in every city, town, and village, but are erected on a small scale in private houses, in which priests are employed, though not generally, to instruct the children of the family. One emperor observed that there were not fewer than 100,000 priests of Fo, and as many priestesses; and that the wisest policy would be to make them marry and get children for the good of the state; that a religion which imposed restraint on the natural passions given to man was undeserving of any regard. No temple can be built without special permission; and they are always used for state purposes by the officers of government, for foreign ambassadors, &c. in their journeying through the country.

The Christian missionaries were long exposed to the same capricious conduct; at one time tolerated or caressed, at another time persecuted or put to death. But after the peace was concluded, permission was obtained to build churches and chapels at the five ports open to Europeans, and all penalties against those Chinese who might profess the Christian religion were annulled. Missionaries found beyond the limits of these towns were not to be chastised or put to death, but to be delivered up to the consuls of their respective countries.

The people are ready enough to embrace any of these religions; but the emperor and his court, and all the officers and magistrates, adhere to the ancient religion, as laid down by Confucius, though there is an obvious leaning of the present Tartar dynasty towards that of Fo or Buddh, which is that of the Lamas of Thibet. The great temple at Gehol, the summer residence of the Tartar sovereigns now on the throne, is named Poo-ta-la (Buddhlaya), the residence of Buddh; but ostensibly he professes and performs the rites of the ancient religion of China; and, at the appointed times, in the capacity of high priest, testifies his gratitude to heaven by offering up the fruits of the earth, and the flesh of certain animals considered as the most useful, as the horse, the ox, the sheep, the hog, the dog, and the domestic fowl. At such times all labour is suspended, the public offices and courts of justice are shut up, and a general festival prevails throughout the whole empire. The vernal ceremony of the emperor holding the plough, is rarely had recourse to in modern times.

The magistrates perform their devotions in the temple or hall dedicated to Confucius; and the usual oblation to his memory is that of a hog, as being the most useful animal known. The ceremonies are performed before a tablet placed on a pedestal, on which is written the name of the philosopher; and at the foot of the pedestal a grave is dug to receive the hair and offals of the animal, in order that no part of it may fall to unworthy purposes. To this temple every magistrate, on entering upon his office, goes with his official brethren, and, in their presence, after the usual homage to the emperor, professes himself a grateful adherent of the doctrines of the illustrious master, which ceremony amounts to the taking of the oaths of fidelity and allegiance to the sovereign. Père Intorcetta, in his treatise *Du Cultû Sinensi*, has translated the whole ceremony from a Chinese author. It is very curious, and bears a marked resemblance to the Catholic ceremony of high mass. They burn incense, pour out libations of wine, chant solemn hymns, accompanied with instruments, read aloud a panegyric on his memory, prostrate themselves before the tablet; and then proceed to feast on the oblations, and to drink each of the "cup of felicity." (Intorcetta *de Cultu Sinensi.*)

The common festival of all savage nations is the time of full moon; and the common people of China are still barbarous enough to hold this festival, by keeping up a noise and riot the whole night. But the grand festival in which all China partakes is that of the new year, when families visit each other, exchange mutual compliments and presents, and abstain from all labour for several days. Every Chinese, however poor, contrives at this time to treat himself and his family with new dresses. His house is newly painted; and tablets of paper, variously shaped, adorn the walls of his apartments. On new-year's day every Chinese strictly watches his own conduct, and every thing that befals him, being persuaded that whatever he does on that day will influence his conduct during the whole year. An universal holiday prevails; all labour is suspended; and nothing but feasting, rejoicing, music, and firing of crackers, prevail, from the midnight preceding the first day of their new year to the ninth day following. During this period all is joy and festivity; yet, in this general scene of mirth and conviviality, to the credit of the Chinese it ought to be noticed, that instances of intemperance or inebriety rarely occur.

The festival of the new year is followed by another of a similar kind, which is called the festival of the lanterns. It commences two days before, and continues two days after, the first full moon of the new year. All China is then in a blaze. Every house and every village, all the shipping on the canals and rivers, every Chinese, however poor, contrives to light up his painted lantern on these days. Transparencies in the shapes of birds, beasts, fishes, and all kinds of animals, are seen darting through the air, and contending with each other; some with squibs in their mouths, breathing fire, and others with crackers in their tails; some sending out sky-rockets, and others rising into pyramids of party-coloured fire; and others again bursting like a mine with violent explosions. A Chinese knows not why, nor makes any inquiries wherefore these things are; it is an ancient custom, and that is enough for him. The inscriptions on these lanterns would seem to point out its religious origin. The most common runs thus, *Tien-tee, San-Sheai, Van-lin, Chin-tsai,* "Oh, heaven, earth, the three limits, and thousand intelligences, hail!" (Barrow's *Travels in China;* Macartney's *Journal;* Du Halde and Grozier.)

The basis, however, of the ancient Chinese religion, and which forms as it were the link that connects it with the government, is the obedience which children owe to their parents, and the respect which is due from the young to the aged, and from the living to the dead, in the strict observance of which all other virtues are concentrated; for these are not to be considered as moral duties only, but as political and religious ordinances. Every family of condition endeavours to build a temple to the memory of its ancestors; and all persons not lost to every sense of duty and devotion visit the tombs of their parents on a certain day in the spring of the year. Never were institutions more innocent in their intention, more blameless in practice, more amiable in their object, or better calculated to produce beneficial results, by recalling pleasing recollections, subduing the passions, and bringing the mind to that calm and tranquil state to which the memory of departed parents usually disposes it. The love and tenderness of departed parents are among the

best impressions of the human mind; "Bind them," says Solomon, "continually about thine heart;" yet the bigoted Dominicans quarrelled with the Jesuits for allowing their Neophytes to honour the memory of departed relations. They represented it as a crime to pluck away the grass and weeds that might have grown around a parent's tomb, and to scatter flowers on a relation's grave; to meet together, and regale themselves with those dainties of which the deceased would have been partaker if alive; fulfilling thus the precept of Confucius, which inculcates the same respect to the dead as if they were living. To support his parents while alive, to bury them decently when dead, to visit their graves at the appointed time, are three indispensable duties of a pious son, by which he proves his gratitude, his sorrow, and his veneration.

There are few families of which some member, in a series of years, has not risen to rank and fortune. Such a one is particularly careful, in obedience to the precept in the ancient book of rites (*Lee-kee*), before he builds a palace, to erect a temple to the memory of his ancestors. To this temple, at particular seasons, all the branches of the family repair together, old and young, rich and poor, high and low, the first officer in the state and the day-labourer. Here all distinction for the time is laid aside, save that of age, which is always reverenced; and he over whose head has passed the greatest number of years takes the precedence in making the oblations, and at the subsequent entertainment given at the expense of the more wealthy members of the family. From five to ten thousand persons sometimes meet together on such occasions.

Whether it be the effect of superstition or of real feeling, or be considered as a religious duty, no people observe so much external attention to the memory of the dead as the Chinese. They even move their coffins from the place in which they have been interred, if the situation be gloomy or the ground swampy. Everywhere in China may coffins be seen exposed on the surface of the ground, because the surviving relation has not been able to fix upon a propitious spot to raise the tomb for its reception. These coffins are generally made of wood sufficiently thick to plank a first-rate man of war. A Chinese usually keeps his coffin by him in the house as a piece of furniture. He contemplates with pleasure the *angusta domus* which is to receive his last remains, and he tries it on just as he would try on a new coat. They believe in a future state of rewards and punishments; but their notions on this head are so vague, and mixed up with those of the Buddhists and Brahmins, that it is difficult to say what were the precise tenets of the ancient sages respecting a future state of existence.

Among the religious superstitions of the Chinese, partly native and partly exotic, may be ranked the almost universal observance of lucky and unlucky days, which are duly registered in the imperial calendar. No marriages, no funerals, no contracts, in short, nothing of importance, must be undertaken on an unlucky day. Even his imperial majesty must be governed in his movements by the Board of Astronomers. Another universal superstition is the *fung-shui*, *wind* and *water*, which relates to the exact line in which the roof of a house must be placed, in order to preserve its own security and its owner's prosperity. The Chinese conceive that a peculiar virtue resides in the odd numbers: thus they reckon *three* powers—heaven, earth, and man; *three* lights—the sun, moon, and stars; the *three* relations—a prince and his ministers, a father and son, a husband and wife. *Fo* has his *three* precious ones, and the *Tao-tse* their *three* pure ones, in which the Jesuits discovered the Holy Trinity. The temples of these sectaries have *three* quadrangular courts, the buildings around which contain the *three* classes of spirits, celestial, terrestrial, and infernal. They reckon *seven* ruling powers—the sun, moon, and five planets; *nine* is as efficient and mysterious a number as among the Hindus, but *five* appears to be the number which is supposed to exert the most extensive influence. The *five* great virtues frequently spoken of in the ancient classical books are, *charity*, *justice*, *good manners*, *prudence*, and *fidelity*. They reckon *five* domestic spirits; *five* elements; *five* primitive colours; *five* seasons of the year, over which are *five* presiding spirits; *five* planets; *five* points of the compass; *five* sorts of earth; *five* precious stones; *five* degrees of punishment; *five* kinds of dress, &c. (*Hist. Gén. de la Chine*; *Mém. Chin.*; Intorcetta *de Cultu Sinensi*; Morrison's *Dict.* &c.)

Language.

It is perhaps impossible for the Chinese themselves to determine what portion of their present mixed religion and superstitions belongs to their ancient institutions, and what has been borrowed from other people. This, however, is not the case with their language. Their speech, and the character in which it is written, have maintained their primitive purity, and may be considered as exclusively their own. This language, more than any thing besides, stamps them as an original people. It has no resemblance whatsoever to any other language, living or dead, ancient or modern. It has neither borrowed nor lent any thing to any other nation or people, now in existence, excepting to those who are unquestionably of Chinese origin. The written character is just now as distinct from any alphabetical arrangement, as it was some thousands of years ago; and the spoken language has not proceeded a single step beyond the original meagre and inflexible monosyllable. Our countrymen have at length fathomed this hitherto mysterious, and, as it was supposed, unattainable language, the acquirement of which had long set at defiance all the talents and industry of foreigners, and was said to employ the whole life-time of the natives: to them it is owing that we are now able to give some intelligible account of it. In fact, those insurmountable difficulties turn out to be altogether visionary. The laudable industry of Dr Marshman and Dr Morrison has supplied us with grammars and dictionaries of this singular language. They have not only placed the treasures within our reach, but given us the key to unlock them, though in an uncouth and unsystematic manner; a defect, however, which has been, in a great measure, remedied by the labours of others. As the subject is almost new in this country, we shall endeavour to give as concise and comprehensive a view of it as our limits will admit, and such as may not only convey a correct notion of the singular nature and construction of the written character, but may be of some use to those who shall engage in the study of it.

The philologists of China speak of knotted cords, twisted from the inner bark of trees, being made use of originally to register events; but as this period is carried back to the fabulous part of their history, it only deserves notice from the remarkable coincidence of a nation having been discovered many thousand years afterwards on a different continent, and the antipodes almost of China, who were actually in the practice of using the same means for the same purpose. The second step towards the formation of a written character, by the invention of the *quoa* or diagrams of Fo-he, is perhaps entitled to as little consideration as the knotted cords. As a language they must have been too complicated, and the supposed use of them too refined, for a people in so rude a state as the Chinese represented themselves to have been in the time of that chief. It is generally thought that the written character was first suggested in the reign of Hoang-tee, the third from Fo-he, and that the figures on a tortoise's back first gave the idea. Dr Morrison says that a person named

China.

Paou-she, who lived about the year of the world 2900, is considered as the father of letters, and that nine tenths of his characters were hieroglyphic; he means to say, rude representations of the thing signified, which, in point of fact, may be considered as the first attempt of all uncivilized people to express their ideas to the eye. At a later period we find several accounts of alterations and new suggestions in the characters, one making them to imitate the lines of the dragon, another the flowing lines of worms and snakes, a third the prints of birds' feet, a fourth of leaves, branches, roots, &c.; all of which would appear to be nothing more than so many attempts to reduce the rude figures of objects to a more convenient and systematic form for general utility. Enough still remains on ancient seals, and vases for sacred purposes, to show the original state, or nearly so, of the Chinese characters, and to trace the changes that have taken place from the *picture* to the present *symbol*. These ancient characters are to be met with in numerous Chinese books; and a collection of them is contained in Père Amiot's *Lettre de Pekin*, from which the following are extracted. They are called the *Kou-wen*, and are the most ancient characters that are known.

 a dragon.  a lion.  an ox.

 an elephant.  a tortoise.

 a fish.  a house.  a branch of a tree.  a window.  a bow.

 to shoot. A multitude of similar description is to be found in books of philology, being obviously the rude representations of the several objects they are meant to express.

From these rude imitations of objects Chinese writers trace the progressive steps to a more abbreviated and convenient form: Thus,  the sun, is now 日.  the moon, now 月.  a mountain, now 山.  a mouth, now 口.  a field, now 田.  a horse, now 馬.  the eye, now 目.  the ear, now 耳.  a chariot, now 車.  a boat, now 舟.  a sheep, now 羊.  a bow, now 弓. The dragon is still a complicated character 龍, and the tortoise 龜.

The qualities of objects could only be marked down by arbitrary signs or symbols, which, however, when once settled by convention, were equally expressive with the pictorial resemblances of those objects. Many modifications, however, such, for example, as crooked, straight, above, below, great, little, &c. were capable of being expressed to the eye by particular characters, appropriate to their modifications.

一 one, 二 two, 三 three, 亅 hooked, 冖 covered, sheltered, protected, &c.; but symbolical representations of this kind could not be sufficiently numerous to embrace all the qualities and modifications of objects.

The first attempt at a regular system of classification of the characters which the Chinese had invented for expressing their ideas, is stated to have been that of dividing them into nine classes, called the *Lee-shoo*, and afterwards into six, called the *Lieou-ye*.

1*st* Class contained all those which had been reduced from the rude picture of the object to a more simple form; as the sun, moon, a man, a horse.

2*d*, Those which pointed out some property belonging to the object; as great, small, above, below.

3*d*, The combination of two or more simple objects or ideas to produce a third, resulting from their union.

4*th*, Those whose names, when sounded, were supposed to imitate the sound of the objects expressed by them.

5*th*, Those which give an inversion of the meaning by inverting the character; and all those used in a metaphorical sense.

6*th*, This class seems to include all those characters that are merely arbitrary, and which cannot be brought under any of the preceding divisions. We shall explain these classes by examples.

This ill-digested and obscure arrangement was soon abandoned for another not much better, namely, that of classing the characters according to their sounds or names. As these names were all monosyllables, and as each monosyllable began with a consonant, with very few exceptions, and ended with a vowel or liquid consonant, the number of such monosyllables was necessarily very limited; by our alphabet, the whole of them might be expressed in about 330 syllables; but as necessity taught the Chinese to employ in early life the organs of speech and hearing, in acquiring a greater nicety than most nations have any occasion for, they were able to swell the number of their monosyllables, by means of intonations and accentuations, to about 1200 or 1300. As soon, therefore, as the number of characters exceeded the number of words, it is evident that any *verbal* arrangement must be attended with uncertainty and confusion; if, for instance, they had 10,000 characters and only 1250 words, the same word must be applied to eight different characters; and as the latter now, in Kaung-hee's Dictionary, exceeds 40,000, each syllable in the Chinese language must, on an average, represent thirty-two different characters; and, in point of fact, there are syllables that give the same name to sixty or eighty different characters.

It is difficult to conceive, therefore, without the assistance of an alphabet, how they could possibly contrive to class the characters in a dictionary according to their *names*, and by what means they could ascertain the name of a character which speaks only to the eye. To discover this, they seem to have had recourse to three different methods. The first was to place at the head of a list of cha-

racters, having the same sounds, some common well-known character, and to mark them severally with their respective intonations. The second method was that which is still used in all their dictionaries. It consists in writing after the character whose sound is sought for, two common characters, of which the initial sound of the first, added to the final sound of the latter, produces a third; as from the *m* of *moo* and the *ing* of *tsing*, is compounded the third or new monosyllable *ming;* and, in the same way, from *ting* and *ke* would be formed *te*, &c. The two characters, so employed, are called *tse-moo*, or "mother characters," and the third produced from them *tsé*, or "the child." The third method was, by means of a modified Sanscrit alphabet, or series of sounds, which was introduced into China since the Christian era, by some priests of Buddh, "to give currency," says one writer, "to the books of Fo." This system is described in the introduction to Kaung-hee's Dictionary, though it is never used, and but very little understood. The Chinese, indeed, reprobate the idea of changing their beautiful characters for foreign systems, unknown to their forefathers. "It appears to me," says one of their writers, "that the people of *Tsan* (Thibet, from whence they derived the system of initials and finals) distinguish sounds; and with them the stress is laid on the sounds, not on the letters. Chinese distinguish the characters, and lay the stress on the characters, not on the sounds; hence in the language of *Tsan* there is an endless variety of sound, with the Chinese there is an endless variety of the character. In *Tsan*, the principles of sound excite an admiration, but the letters are destitute of beauty; in China, the characters are capable of ever-varying intelligible modifications, but the sounds are not possessed of nice and minute distinctions. The people of Tsan prefer the sounds, and what they obtain enters the ear; the Chinese prefer the beautiful character, and what they obtain enters the eye." And the Chinese are right; for, unless with their character they gave up their monosyllables, they might almost as well have no written language at all; as, if written alphabetically, it would be wholly unintelligible. The written character assists their meagre monosyllables, an alphabet would completely destroy them. The written character, however, has probably been the means of fixing the spoken language in its primitive monosyllabic form, as the least change or inflexion of the spoken language must at once and for ever destroy the connection between it and the written character; and this connection, by the way, is no mean proof of the antiquity of the present symbols. (Pref. to Morrison's *Dictionary;* Barrow's *Travels in China.*)

These symbols are now reduced to a regular and complete system, which renders the study of the language comparatively easy. A certain number of characters have been selected, which the Chinese call *Tse-poo*, "superintending or directing characters," and sometimes *Shoo-moo*, or the "eyes of the book," which, considering them as composing an index to the book, is no bad name. The Jesuits have given them the name of *keys*, and sometimes *elements* or *radicals*, there being no character in the whole language, into the composition of which some one or other of them does not enter. This number, according to the classification now in general use, consists of two hundred and fourteen, and they are divided into seventeen chapters or classes; beginning with those keys or elements that are composed or formed of *one* stroke of the pencil, and ending with those (of which there is only one) composed of seventeen strokes. Plates CLXX. CLXXI. CLXXII. comprehend the whole of these keys or elements, with their several names and significations. When these two hundred and fourteen keys or elements have once become familiar to the eye, there is no great difficulty in detecting them in any of the characters into which they may enter, and without some one or more of which no character can be formed. They will be found to stand more frequently on the left side than on any other part of the character, though they also take their stations sometimes on the right, sometimes in the middle, frequently at the top, and occasionally at the bottom; but a little practice and a ready knowledge of these keys will point them out at once. Thus, in

1. 便 *peen*, "convenient," the key, 亻 *jin*, "man," is on the left.
2. 助 *tsoo*, "to assist," has the key, 力 *lee*, on the right.
3. 全 *tseun*, "the whole," has the key, 入 *joo*, at the top.
4. 兵 *ping*, "a soldier," has the key, 八 *pa*, at the bottom.
5. 愛 *gai*, "to love," has its key, 心 *sin*, in the middle of the compound.

The dictionaries are divided into seventeen sections, headed respectively by the seventeen classes or keys, commencing with that class which has its keys of one stroke, and ending with that which is composed of seventeen strokes. The characters which each key governs, or to which it serves as the index, are also divided into classes, according to the number of strokes they contain, beginning at *one*, and proceeding regularly to the greatest number that any one is found to contain, *exclusive of the key;* and this number, together with the key character, being marked at the top of every page in the dictionary, affords a clue by which any character in the language may be turned to immediately, having first ascertained the *key*, and the number of strokes in the remaining part of that character. Thus, in the above examples, the character *peen* will be found under the key *jin*, and in the *seventh* section, there being *seven* strokes exclusive of the key; in the second, under the *fifth* section of the index *lee;* the third under the *fourth* section of the index *joo;* the fourth under the *fifth* section of the key *pa;* and the fifth under the *ninth* section of the index *sin*.

This classification of the characters is extremely simple and easy; the chief object of it would appear indeed to be, like the Linnæan system, that of giving facility to the finding in the dictionary the character that may be wanted. The nature of Chinese symbols admitted, however, of a more beautiful, perfect, and philosophical arrangement, and might, indeed, have been made the most rational and complete system of pasigraphy or universal character that has yet been attempted. It would seem, indeed, that the Chinese had this idea once in view; but, either through ignorance, pride, or caprice, they have entirely marred the plan, and nearly lost sight of it altogether. In the original adoption of the *shoo-moo*, or "book's eyes," namely, the *poo* or keys, they selected no less than 479 to serve as indices to the characters, the whole of which were marshalled under nine divisions. The *first* had a few only, consisting of a single line. The *second* embraced celestial objects, as the sky or firmament, the sun, moon, stars, clouds, rain, thunder. The *third*, terrestrial objects, as

earth, water, metals, hills, rivers; the *fourth*, man, and all the animal functions; the *fifth*, moving things, including all the rest of the animal creation; the *sixth*, the vegetable world; the *seventh*, productions of art and human industry; the *eighth*, miscellaneous; and the *ninth*, characters of a double genus, whose classification could not well be ascertained. Though this was a complicated, and in some degree an arbitrary classification, yet it comprehended a principle which, if it had been adhered to in simplifying the arrangement of the characters, the Chinese might have challenged the world to produce so beautiful and so philosophical a language as their own. This system, called the *Leu-shoo*, is that stated by Dr Morrison to have been invented by *Paou-she*.

After this the 479 keys or elementary characters were reduced to 214, and the characters themselves arranged under six divisions, as before mentioned, the nature of which will be best explained by a few examples to each; and they will tend to show how much more might have been accomplished in this practical approach to an universal character.

1st Class. The rude representation of the object may now be considered as no longer existing; but this class consists generally of simple characters, and almost all the great objects of nature are found among the keys or elements which enter into their composition: this may be called the Imitative Class.

2d Class. Under this class are comprehended those characters which point out the quality or property of an object, as 上 *shang*, above. 下 *shea*, below. Thus also 一 *ye*, one, is used to represent unity, concord, and the like; 丨 *kuan*, straight, upright; 亅 *qûay*, hooked; and generally characters whose meaning can be extended, in a metaphorical sense, as far as the object represented would admit of being so applied; as, for instance, a line drawn through a square thus, 中, signifies *middle*, or any thing divided into two parts; while the same character, in a figurative sense, expresses moral rectitude, good dispositions, and so forth. This class may therefore be called the figurative.

3d Class. Under this class might have been ranked all those compound characters which, if the numbers were properly selected, would have given that peculiar beauty and expression to the language which, even in its clumsy and imperfect state, the Chinese still pretend to feel, by employing significant characters, each of which should be connected with the idea to be conveyed by their union. One half of the language, at least, might have been thus composed, and might have presented a series of symbols, every one of which would have been intelligible to the eye; whereas not one sixth part at the most, some say not one tenth, of the compounds, have any relation to their component parts. A few examples will serve to show how much might have been done by attending to a philosophical composition of the compounded characters. Thus, 亻 *jin*, man, and 言 *yen*, word, forms the compound 信 *sin*, sincere: 日 *je*, the sun, and 月 *yué*, the moon, 明 *ming*, splendour: 中 *tchung*, middle, and 心 *sin*, heart, 忠 fidelity: 亻 *jin*, man, and 田 *tien*, a field, 佃 *tien*, a farmer: 田 *tien*, a field, and 力 *lee*, strength, 男 *nan*, male kind: 耳 *eul*, the ear, and 止 *tchei*, to stop, 耻 *chee*, shame: 口 *koo*, mouth, and 金 *kin*, gold, 唫 *kin*, volubility of speech: 言 *yen*, word, and 寺 *shee*, temple, 詩 *shee*, verses, poetry: 分 *fen*, to divide, and 貝 *pei*, riches, 貧 *pin*, poverty: 囗 *yu*, an enclosure, and 人 man, 囚 *cheu*, a prisoner: 禾 *ho*, rice, and 口 *koo*, mouth, 和 comfort: 一 *ye*, one, and 大 *ta*, great, 天 *tien*, heaven or God: 竹 *tcheou*, a bamboo, and 即 a slap, 節 *chee*, to govern: 喬 *keu*, high, and 馬 *ma*, horse, 驕 *kheu*, proud.

4th Class. The characters arranged under this class are such as embrace both the *meaning* of the object and the *sound* it is supposed to utter; and it includes objects animate and inanimate. The characters are all compounded of one of the elements to express the genus, added to one imitative of the sound uttered by the object. Thus, 氵 *shuee*, water, added to 工 *koong*, forms the character 江 *kyang*, which denotes a rapid stream, expressive, as they say, of water rushing with violence; and 可 *ho*, a river, with 氵 *shuee*, water, makes the compound 河 *ho*, a river, the name of which is said to imitate the sound. To this class may also be added those objects in the animal kingdom whose generic character

can be expressed by one of the elements, and the species by some other character that shall convey its name merely by the sound of the latter character. If, for instance, to the generic character, *bird*, be added another character whose name and sound is *go*, the new compound will also be named *go*, and will signify a goose; if to the same character *bird* be added another named *ya*, the compound will be also *ya*, and will signify a *duck;* if to the generic character *tree*, be added the appellative *pe*, the compound will be named *pe*, and signify a cypress; with *tao*, it will be called *tao*, and signify a walnut tree; and with *lieou* it will retain the name of *lieou*, and signify a willow. In this class may also be comprehended all foreign names written in the Chinese characters, to which, in order to mark them as destitute of meaning, they usually annex on the left side the character signifying *mouth*. Thus the English word *strong* would require three characters, *se-te-lung*, and, with the *mouth* prefixed, would be written thus,

吐 *se* 嘚 *te* 嚨 *lung;* but these characters, if the *mouth* was taken away, would be read by a Chinese, the *magistrate procured a dragon*.

5th Class. Consists of an inversion of the sense by an inversion of the whole or some part of the character; or it alters the meaning by giving a different name to the same character; or, lastly, the characters which compose it are used in a figurative or metaphorical sense. An European cannot readily comprehend the illusions or allegories that are frequently contained in a single character, though probably they are not more numerous than those which are found in any of the languages of Europe, rendered easy, and indeed not perceived, by early habit. The combined characters of the sun and moon, which, in a physical sense, expressed brightness, brilliancy, splendour, are also, in a moral or metaphorical sense, noble, illustrious, famous. The characters *heart* and *dead* form a third, which signifies *forgetfulness; fickleness* or *levity* is represented by a *girl* and *thought; attention*, by the *heart* and *totality; antiquity*, by *mouth* and the numeral *ten; to flatter*, is compounded of *word* and *to lick; to boast*, of a *mountain* and *to speak*. The *wife of a magistrate* is used metaphorically for *an accomplished lady*, a *wild boar* for *courage*, a *tiger* for *ferocity:* and so of others. It may be observed, however, that these compounds are disregarded by the Chinese in general, just as many words in the European languages are in common use, without any reference to their etymology.

6th Class. These characters are either arbitrary, or formed out of some distant or local allusion, most of which are inexplicable to the Chinese themselves. Thus, a *bamboo* and *heaven* form a compound, which signifies *to laugh; water* and *to go*, compose a character signifying *law; wood* and the *sun* form the word *east;* the character *woman* three times repeated may signify *adultery*, or *communicating with an enemy*. These may or may not be arbitrary combinations. We can explain why the compound of *wine* and *seal* should signify *marriage*, from the circumstance of *wine* being presented by the bridegroom to the bride as the *seal* to the contract; and why that of *girl* and *upright* should signify *concubine*, or inferior wife, because such a one must *stand* in the presence of her lord and master; also why that of *woman* and *sickness* should signify *death*, because when the sovereign was sick, and given over by the physicians, he was left to *die* in the hands of *women;* but by far the greater part are utterly inexplicable.

Such, by the Chinese account, is the philosophy of their language; not very clear, it must be confessed, nor exactly calculated for practical facility; but, at the same time, approximating to a very beautiful system. That system has, to a certain degree, been preserved in the modern classification under the 214 elements. Thus, under the element or key which signifies *heart*, we shall find all the characters arranged expressive of the sentiments, passions, and affections of the mind, as grief, joy, love, hatred, anger, and the like. The element *water* enters into all the compounds which relate to the sea, rivers, lakes, swamps, depth, transparency, and so forth. The key or element *plant* takes in the whole vegetable kingdom. *Yen*, a *word*, enters into the composition of those characters which relate to reading, speaking, studying, debating, consulting, trusting, and the like. The handicraft trades, laborious employments, and a great number of verbs of action, have the element *hand* for their governing character. All this is perfectly intelligible; but, on casting a glance over the elementary characters, it will be seen that fully one half of them are utterly incapable of being formed into any generic arrangement; and one is surprised and puzzled to conjecture by what accident they could possibly have been included among the elementary characters, or even as indices to characters. The fact is, that, of the 214 characters thus employed, not more than 150 can be considered as effective; the rest being very rarely employed in the combination of characters. Of the 40,000 characters, or thereabouts, contained in the standard dictionary of the language, sixty of the elements govern no less than 25,000. The most prolific is the element *grass* or *plants* (No. 140), which presides over 1423 characters; the next *water* (No. 85), which has 1333; then the *hand* (No. 64), which has 1012. After these follow, in succession, the *mouth*, *heart*, and *insect*, each having about 900; then a *word*, a *man*, and *metal*, each exceeding 700; next a *reed* or *bamboo*, a *woman*, *silk*, a *bird*, *flesh*, *mountain*, and so on, each governing from 500 to 600. In the modern classification, therefore, of the characters, though probably intended as a more convenient instrument for reference in the dictionaries, so much of the natural arrangement has been preserved as will serve to convey to the eye at once the general meaning of a character; at least of such characters as are governed or fall under any of the principal elements. They have even gone beyond this. Feeling how much more capable of nice discrimination the eye is than the ear, the written character has been employed to mark distinctions, which, in an alphabetic language, would be impossible. Instead of the modifications of time, place, age, colour, and the like, by which sensible objects are affected, being expressed by so many epithets or additional characters, in the several stages of their existence, or the lights in which they may be viewed, the Chinese employ only one single character for each several modification of which an object or idea may be susceptible, whether in the physical or intellectual world. Thus they have the key or elementary character for *water* simply, another under that key for *salt* water, a third for *fresh* water, a fourth for *muddy* water, a fifth for *clear* water, and so on for *running*, *standing*, *deep*, *shallow*, and every other qualification that water is capable of receiving; and the same of love, anger, jealousy, ambition, &c. all of which are expressed by their respective symbols, combined with the element *heart*.

The colloquial language is not less singular than the symbolical characters, being, like the latter, exclusively their own, and having borrowed nothing from, nor lent anything to, the rest of the world. The 330 monosyllables, each beginning generally with a consonant, and ending with a vowel, or liquid, or the double consonant *ng*, which, as we have observed, complete the catalogue of words in their language, are, by means of four modifications of

sound, or intonation to each syllable, extended to about 1300; beyond which, not one of them is capable of the least degree of inflexion, or change of termination; and the same unchangeable monosyllable acts the part of a noun substantive and adjective, a verb and a participle, according to its collocation in a sentence, or the monosyllables with which it is connected. It is neither affected by number, case, nor gender; mood, tense, nor person; all of which, in speaking, are designated by certain affixes or prefixes to mark the sense. Thus the genitive of *love*, *gai*, is expressed by the particle *tié* set after it, as *gai-tié*, of love; the dative by *eu-gai*, to love; and the ablative by *tung-gai*, by or from love. The plural is expressed sometimes by the repetition of the noun, as *yin*, a man; *yin-yin* men; *to-yin*, many men; *to-to-yin*, all men. Certain particles of number are also employed before nouns, which vary according to the nature of the noun. Thus *man* has *ko*, as *san-ko-yin*, three men; most other animals *tchee*, as *liang-tchee-ma*, two horses; bodies with extended surfaces *tchiang*, as *ye-tchiang-tchoa*, one table. The number of particles so employed amount to about thirty. The final expletive *tsé* is added to nouns, not only to distinguish them from adjectives, but for the sake of euphony; as *pie-tsé*, a pipe; *fang-tsé*, a house; *ya-tsé*, a chair; the particle *tié*, the same which designates the genitive of the substantive, is set after the adjective or pronoun; as *ta*, he, with *tié* after it, becomes a possessive, *ta-tié*, his, &c. The gender of nouns is seldom necessary to be expressed in conversation, unless for the sake of removing ambiguity. When this is the case, *nan* and *neu* distinguish male from female, as *nan-yin*, a man; *neu-yin*, a woman. Adjectives admit of comparison in various ways. Commonly *ye-yang* is used to express the positive, as *ye-yang-hoa*, as good as, or equally good; the preposition *keng* forms the comparative, as *keng-hao*, better; and, with the addition of *toa* following it, the superlative, as *hao-toa-keng*, the best. A repetition of the positive also marks the superlative, as *hao-hao*, very good.

The personal pronouns *go*, *ne*, *ta*, I, thou, he, are made plurals by the addition of *mun*, as *go-mun*, *ne-mun*, *ta-mun*, we, ye, they. *Che-ko*, this, and *no-ko*, that, are the demonstratives.

The only tenses of the verb necessary to be distinguished are the present, past, and future. The past is formed by the particle *leau* set after it, and the future by *yau*, will or determination, or *tchong lai*, time to come. Thus, *go gai*, I love; *gi gai leau*, I have loved, or did love; *go yau gai*, or *go tchang lai gai*, I shall hereafter love. The negatives generally in use are *mo* and *poo*; as *yeu*, to have; *mo yeu*, not to have; *hao*, good; *poo hao*, bad.

Such is the simple and inartificial language spoken by a mass of people equal in number to that of the whole of Europe. Its imperfection must be obvious when it is considered that 40,000 distinct characters are represented by about 1300 monosyllabic sounds; but, as a good composition is intended only to be seen, the particles and expletives necessary in familiar conversation are all omitted. If such writing were read aloud it would scarcely be intelligible, and, at any rate, full of ambiguity. Indeed, it frequently happens, that, in reading a paper, the auditors are assisted by the reader making, with a motion of his hand in the air, or with his fan, the shape of the character, or, at least, the key of it, to remove any ambiguity. This, in conversation, is obviated by the use of certain expletives. For instance, when a man is speaking of his father, which is *foo*, a monosyllable that has seventy or eighty other meanings besides that of father, a Chinese will say *foo-chin*; and, instead of *moo* for mother, *moo-chin*. The syllable *chin*, signifying *kindred*, removes at once all doubt as to the meaning of the speaker; but the *chin*, in writing, is wholly unnecessary, and would be left out, the character signifying *father* being totally different from any other character that may have the name of *foo*. A foreigner, not always aware of this, is liable to many equivoques in speaking the language. Thus a missionary, requesting to be allowed to pass the night at a peasant's house, asked for a *young girl* to sleep with, when he meant only to ask for a *mat*; and another told the emperor he served *three wives*, when he meant to say so many *churches*. (Barrow's *Travels in China*; Morrison's *Dictionary*; Marshman's *Clavis Sinica*; Fourmont's *Meditationes Sinicæ*, &c.)

One of the most remarkable features of Chinese policy is the very general diffusion of education, and the encouragement that from a very early period has been given to the cultivation of letters. The importance of educating the people was acknowledged and acted upon in China even before the time of Confucius, and at a period when no other nation had any established system for general education. Schools and colleges are established in all parts of the empire, and education is very generally diffused among all classes of the people; indeed, almost every man in this vast empire can read and write sufficiently for the ordinary purposes of life. The education of females, though less encouraged, is yet not entirely neglected. The course of instruction to be followed, and the books to be studied, are prescribed by law; and to this in a great measure is to be attributed the fact, that so little progress has resulted from the general diffusion of education. The object of the government is to impart the knowledge already possessed to as large a portion as possible of the people—not to extend the bounds of knowledge itself. The peace of the kingdom has no doubt been much promoted by the general diffusion of knowledge among all classes. Education is inculcated by positive precept, as well as encouraged by open competitions for the highest rewards. One prime motive for every Chinese to educate his sons must be the consciousness that he is liable to punishment for their misdeeds, while he receives credit for their merits. How such a system must operate as a stimulus to education is sufficiently obvious. The great encouragement to the cultivation of letters, however, is, that they are professedly the sole channel of introduction to political advancement in the state, and to the acquirement of office, rank, and honours, of almost every description. The pursuits of literature throw open the highest offices in the state to the lowest of the people; and it would appear that honours and offices are very generally bestowed according to merit. The pressing necessities of government, more particularly of late, have obliged it to have recourse to the selling of offices; but this practice does not seem to be extensively carried on. Exceptions may also occasionally be made regarding particular favourites, or Tartars connected by blood with the imperial family. The prospect of such rewards brings forward a number of competitors for offices, and a taste for letters is almost universally diffused among all ranks and denominations.

The degrees of literary merit are four, viz., *Sew-tsee*, "men of cultivated talent;" *Keu-jin*, "elevated persons;" *Tzin-sze*, "advanced scholars;" and *Han-lin*, "the forest of pencils," or national institute. The examinations for the first title takes place in the country towns; for the second, in the provincial capital; for the third, in the imperial capital; and for the fourth, in the emperor's palace. The examinations are very strict, and only a few out of numerous candidates receive titles. After undergoing certain preliminary examinations by the superintendent of the district, the scholar is recommended as a candidate for the first degree, the examinations for which take place twice every three years. The trial takes place in the county hall, which is divided into compartments just sufficient for the accommodation of each student. They receive themes on which

to write both in prose and verse, and are strictly guarded by soldiers to prevent their receiving any assistance. Those who have passed the first examination may become competitors at the second, which takes place once every three years. The examiners on this occasion are the imperial chancellor and the chief officers of the province; and the aspirants usually number about 10,000, who are confined in cells, and guarded as already mentioned. The number that receive this degree are only about 72 in each province. The third degree is the result of a still more rigorous examination at the capital. Here, also, about 10,000 candidates enter the list, and after being examined in the way described, about 300 of these are dignified with the title of *Tsin-sze*. The fourth degree follows a very close examination of those who have already obtained the third, and takes place in presence of the emperor. The successful candidates on this occasion obtain liberal salaries from the emperor, and are employed to deliberate on all questions regarding politics and literature, to prepare public documents, &c. The three highest candidates are forthwith mounted on horseback, and paraded for three days round the capital, signifying that "thus it shall be done to the man whom the king delighteth to honour." The chief of the three occupies the most enviable post in the nation, and yet a post to which all are eligible, and to which all may aspire.

To succeed at any of these examinations, it is necessary to put forth extraordinary exertions. Each candidate is expected to know by heart the whole of the Four Books and Five Classics, as well as the authorized commentaries upon them, to be familiar with the history of China from the earliest times, and to be well acquainted with the most celebrated authors of antiquity. The chief excellency of their essays consists in introducing as many quotations as possible from ancient authors; but they are deprived of all books and writings, being expected, as their phrase is, "to carry their books in their stomachs." All this can only be attained by great application and perseverance. The first five or six years at school are spent in committing the canonical books to memory; another six years are required to collect phrases for a good style; and an additional number of years spent in incessant toil are needed to insure success. (Medhurst's *China*; Davis's *China*.)

As a further encouragement to literature, the press is left free to all, and any one may print what he pleases, taking his chance for the consequences. That this unrestrained liberty of the press should exist in one of the most arbitrary governments that is known, is a remarkable phenomenon in the history of nations. No previous license is required, no restrictions are imposed, though the publication of books is made amenable to certain regulations established by law. In general, crimes, and their corresponding punishments, are clearly and minutely defined in the *Laws of China*; but the law which regards the press is left, perhaps intentionally, vague and uncertain. According to the *Leu-tee*, "whoever is guilty of editing wicked and corrupt books, with the view of misleading the people, and whoever attempts to excite sedition by letters or handbills, shall suffer death by being beheaded; the principals shall be executed immediately after conviction, but the accessaries shall be reserved for execution at the usual season." And further, "all persons who are convicted of printing, distributing, or singing in the streets, such disorderly and seditious compositions, shall be punishable as accessaries."

These severe laws are by no means a dead letter; numbers have been executed in virtue of them. Three unfortunate authors were punished with death, and their families banished, by that great patron of literature, Kienlung, in three consecutive years, for publishing books that no European government would have deigned to notice; but political discussions are least of all palatable to despotic governments, and are easily brought under the charge of constructive treason, a crime that in China is never pardoned.

The instances, however, that occur of severity of punishment seem to have little effect in diminishing the number of publications, and are not more hostile to the liberty of the press in China than the occasional punishment of a jail for libel is destructive of that liberty in England. A writer in a popular periodical journal says, that thousands of novels and moral tales, amusing stories, laughable comedies, moral precepts from ancient sages, and exhortations from living sovereigns; popular songs, fables, and romances; books of receipts to heal the sick and to pamper the appetite; predictions of the weather, and of good or bad luck; manuals of devotions, of religious rites, and rules of good breeding; almanacs and court calendars,—are the lighter sort of publications which issue daily from the press in Pekin and other great cities of the empire. All ranks in China read, and find it a cheap luxury; the more bulky and expensive works, as those on history, philology, and jurisprudence, are sometimes published by subscription, but are supplied to the libraries of the magistrates by the government. Libraries are seldom formed to any great extent by individuals. The grand collections of history, philosophy, and other standard national works, published by the direction of the sovereign, under the superintendence of the *Han-lin*, are distributed to the princes of the blood, the viceroys of provinces, presidents of departments, and to the learned of the empire, but are rarely met with in the libraries of private individuals. "Books," says Mr Medhurst, "are multiplied at a cheap rate, and to almost an indefinite extent; and the very peasant and pedlar have the common depositories of knowledge within their reach. It would not be hazarding too much to say, that in China there are more books, and more people to read them, than in any other country in the world. Amongst the 360 millions of Chinamen, at least two millions are *literati*." (*China Opened.*) A further idea of the extent of the Chinese literature may be gathered from the fact, as stated by Williams, that the catalogue of all their books in the four libraries, affording a complete and succinct synopsis of the contents of the best books in the language, extends over 112 volumes 8vo, of about 300 pages each, and probably contains the names of upwards of 20,000 works. The books are arranged into four divisions, viz., classical, historical, scholastic or professional writings, and belles-lettres. There is not, however, much that is original in their books, the Chinese generally believing that all that is known, or that is to be known, has already been discovered and communicated by the ancient sages. Many of their works, however, on history, biography, statistics, &c., are very valuable and interesting. Their biographical works are numerous and interesting. They have also a very interesting work entitled *The Complete Antiquarian Researches of Ma Twanlin*, who lived A.D. 1275. It is a very extensive and profound work, containing researches upon every matter relating to government, and extending through a series of dynasties which held the throne for nearly 4000 years. Remusat says, that "this excellent work is a library by itself; and if the Chinese literature possessed no other, the language would be worth learning for the sake of reading this alone."

The most celebrated compositions in the Chinese language are the "Five Classics" and the "Four Books," most of which were compiled by Confucius and his disciples. The Five Classics are the *Yihe-king*, "Book of Diagrams;" the *She-king*, "Collection of Odes;" the *Le-ke*, "Record of Ceremonies;" the *Shoo-king*, containing the history of the three first dynasties; and the *Chun-tsew*, an account of

China.

the life and times of Confucius. Of the Four Books, the first two,—*Chung-yung*, "The Happy Medium," and *Taheo*, "The Great Doctrine,"—were written by Tsze-sze, the grandson and disciple of Confucius; the third, called the *Lun-yu*, "Book of Discourses," is the production of the different disciples of the sage, who recollected and recorded his words and deeds; while the last of the Four Books was written by Mencius, the disciple of Tsze-sze, and bears the name of its author. The text of these nine books is equal in bulk to that of the New Testament; and it is not hazarding too much to say, that were every copy annihilated to-day, there are a million of people who could restore the whole of it to-morrow. (Medhurst's *China.*)

To acquire a knowledge of the Chinese language is not so difficult a matter as many suppose. No doubt, to understand it thoroughly, to become familiar with its style, and to speak accurately its delicately marked tones, is, as in any other language, a work of great labour and difficulty; but to acquire a partial knowledge of it, so as to be able to speak it intelligibly and read it with considerable ease, is by no means a difficult task. In proof of this, we might allude to the fact, and there are many similar, that Sir John Davis, before he had been two years in Canton, had acquired a sufficient knowledge of the language to enable him, with the occasional assistance of a native, to translate several pieces of poetry, two or three novels, and, what was probably the most difficult of all, a Chinese drama, subsequently published in London. The numerous grammars, dictionaries, and translations that now exist tend materially to diminish the labour of learning the language. Europeans have been deceived as to the vast number of characters in use among the Chinese. Ainsworth's or Johnson's *Dictionary* contains about 45,000 words, and though the great Dictionary of Kaung-hee may contain nearly as many, it includes many obsolete and synonymous characters. It is probable that the total number of characters in the language sanctioned by good usage does not exceed 25,000, and even this latter sum contains many thousands of characters seldom to be met with. "It may be safely said," says Williams, "that a good knowledge of 10,000 characters will enable one to read any work in Chinese, and write intelligibly on any subject." The nine canonical works contain altogether only 4601 different characters. (Williams' *Middle Kingdom.*)

Poetry.

The origin of Chinese poetry is indicated by the component parts of the character employed to express it,—*words* of the *temple*,—short-measured sentences, delivered as instructions to the people: such are those in the ancient writings, and such chiefly are the moral maxims of Confucius. It is so far from being true, as Grozier flippantly asserts, "that a learned man writing good verses would be considered in the same light as a dragoon officer playing well on the fiddle," that there are few men having any pretensions to learning who do not write verses. The several odes and didactic poems of Kien-lung were quite sufficient to make poetry fashionable, if there were no taste for it among the people; but all are fond of poetry. We have before us the translation of an Ode on England and London, written in 1813, by a common Chinese servant, brought over by a gentleman from Canton, in which are many just observations, with accurate and concise descriptions. The climate, he says, is cold, and people live close to fires; and the houses are so lofty that you may pluck the stars. Kaung-hee made the same observation to the Jesuits, and supposed that Europeans lived, like birds, in the air, for want of space to build upon. Our Chinese proceeds to say, that the virtuous read their sacred book, and (*pe lee to Got*) pray to God; that they hate the French, and are always fighting with them; that the little girls have red cheeks, and the ladies are fair as the white gem; that husbands and wives love each other; that the playhouses are shut in the day and open at night; that the players are handsome, and their performance delightful. The nature of the character is well adapted to that expressive kind of poetry which pleases the eye of a Chinese, by selecting such as are most comprehensive, or such as allude to some ancient custom, or such as can be used in a metaphorical sense: for instance, "the rushing of water down a precipice roars like thunder," is expressed by a single character; and that which signifies "happiness," reminds him, by its component parts, of his guardian angel, of the benefits of union and concord, and of plenty, signified by a mouth over a cultivated field. The intercalary moon is expressed by the character *king* placed in that of *gate*, because on such an occasion it was the ancient custom for the king to stand in the door. Thus, also, a *man* and *word* express *fidelity*; *fire* and *water*, *calamity*; *eye* and *water*, *tears*; *heart*, *truth*, and *words*, *sincerity*; *word* and *nail*, a *bargain*; *beauty* and *goodness* are signified by a character composed of a young virgin and an infant; a *flatterer*, of *word* and to *lick*, a kingdom is expressed by a *square* or *space*, within which is a *mouth* and *weapons*, alluding, perhaps, to *arms* and *counsel*, being the best protection of a state. But though the sense of seeing seems to be that which is rather addressed in Chinese poetry than the sense of hearing, yet they have their rules both of rhyme, and measure, and quantity, the last of which is given by the tones or accentuations, which are entirely modern. Mr (now Sir John) Davis has published a very curious work, in which he enters into a critical examination of the rules, and the merits and the defects of Chinese poetry. Among the specimens of ancient poetry from the *Shoo-king*, the following is an address of the emperor *Chun* to his ministers:—

Koo, koong khée tsai
Yuen shyeu khée tsai
Puh koong hee tsai.

When the chief ministers delight in their duty,
The sovereign rises to successful exertion,
A multitude of inferior officers ardently co-operating.

To which the ministers responded in the same strain:—

Yuen shyeu ming tsai
Koó koong lyang tsai
Shyu tsé khang tsai.

When the sovereign is wise,
The ministers are faithful to their trust,
And all things happily succeed.

The *Shee-king*, or Collection of Odes, upwards of three hundred in number, is of a higher strain, one of which, on marriage, has been beautifully versified by Sir William Jones. The lines consist of no definite number of syllables, some containing three, some seven; but the greater part are limited to four. The rhyme is equally irregular, some having none, in others every line terminating with the same word; sometimes six lines rhyme in a stanza of eight, occasionally four, three, and sometimes only the first and last. Four lines in the stanza, and four characters in each line, seem to be the most common measure in ancient poetry; but many odes of the *Shee-king* extend the stanza to eight, ten, or twelve lines. At present, *five* and *seven* characters are the most common number in the line; the former having the stanza of sixteen, the latter generally of eight; the rhyme seems to be entirely arbitrary. There is not much sublimity of mind or depth of thought in these odes; but they abound with many touches of nature, and are exceedingly interesting and curious, as showing how little change time has effected in the manners and sentiments of this singular people.

We give the following from Grozier's collection, as no unfavourable specimen of modern poetry. It may be called the Contented Philosopher.

"My palace is a little chamber, thrice my own length; finery never entered it, and neatness never left it. My bed is a mat, and the coverlid a piece of felt; on these I sit by day, and sleep by night. A lamp is on one side, and on the other a pot of perfume. The singing of birds, the rustling of the breeze, the murmuring of a brook, are the only sounds that I hear. My window will shut, and my door open,—but to wise men only; the wicked shun it. I shave not, like a priest of Fo; I fast not, like the Tao-tsé. Truth dwells in my heart, innocence guides my actions. Without a master, and without a scholar, I waste not my life in dreaming of nothings, and in writing characters, still less in whetting the edge of satire, or in trimming words of praise. I have no views, no projects. Glory has no more charms for me than wealth, and all the pleasures of the world cost me not a single wish. The enjoyment of ease and solitude is my chief concern. Leisure surrounds me, and bustle shuns me. I contemplate the heavens, and am fortified. I look on the earth, and am comforted. I remain in the world without being in it. One day leads on another, and one year is followed by another; the last will conduct me safe to port, and I shall have lived for myself."

The drama.

Dramatic entertainments are in China, as in Europe, closely connected with poetry. The songs and recitative, in the lighter pieces, abound with characters of double meaning and equivocal expression; but are generally so contrived that, while the written characters shall bear one sense, the sound shall convey to the ear another; and these subterfuges are resorted to in order to avoid that punishment which the magistrates would be compelled to inflict for a breach of the law respecting public decorum, in the publication or exhibition of any thing directly and unequivocally obscene; and yet real life is represented on the stage, without any of its polish or embellishments. All acts, however infamous or horrible, are exhibited on the stage,—a murder or an execution. Whether the culprit be condemned to die by the cord, by decollation, by being cut into ten thousand pieces, or by being flayed alive, the spectators must be indulged with a sight of the operation. Nor do they stop here. Those functions of animal life over which decency requires a veil to be thrown, are exhibited in full display; many of them so gross and indelicate, so coarse in the dialogue, and so indecent in the scenic representation, that foreigners who have witnessed them have retired from the theatre in disgust.

It is no excuse that these obscene exhibitions were performed for the amusement of foreigners, whom they are pleased to consider as barbarians. The representation of real life, in its ugliest dress and most hateful deformities, could only be conceived by a people of depraved habits and a vicious taste. Of the court exhibitions we have amusing descriptions in the journals of Lord Macartney, Van Braam, and De Guignes. Lord Macartney describes the theatrical entertainments to consist of great variety, tragical as well as comical; some historical, and others of pure fancy, "partly in recitative, partly in singing, and partly in plain speaking, without any accompaniment of instrumental music, but abounding in battles, murders, and most of the usual incidents of the drama." The grand pantomime followed, the subject of which his lordship conceived to be "The Marriage of the Ocean and the Earth. The latter exhibited her various riches and productions, dragons, and elephants, and tigers, and eagles, and ostriches, oaks and pines, and other trees of different kinds. The ocean was not behind hand, but poured forth on the stage the wealth of his dominions, under the figures of whales and dolphins, porpoises, and leviathans, and other sea monsters, besides ships, rocks, shells, sponges, and corals, all performed by concealed actors, who were quite perfect in their parts, and performed their characters to admiration." These marine and land productions paraded about for a while, when the whale, waddling forward to the front of the stage, took his station opposite to the emperor's box, and spouted out of his mouth into the pit several tons of water. "This ejaculation," says his lordship, "was received with the highest applause; and two or three of the great men at my elbow desired me to take particular notice of it, repeating at the same time, *Hao, kung hao! charming, delightful!*" After this, they were entertained with tumbling, wire-dancing, and posture-making; and the amusements of the morning concluded with various fire-works, which were much admired for their novelty, neatness, and ingenious contrivance.

The Dutch ambassadors were chiefly entertained by the feats of jugglers and posture-makers; after which there was a kind of pantomimic performance, the principal characters of which were men dressed in skins, and going on all fours, intended to represent wild beasts. After them were a parcel of boys habited like mandarins, who were to hunt these animals. "This extraordinary chase, and the music and the rope-dancing, put the emperor into such good humour, that he rewarded the performers very liberally; and the ladies behind some Venetian blinds appeared, from their tittering, to be equally well entertained."

An eclipse happened, which kept the emperor and his mandarins the whole day devoutly praying the gods that the moon might not be eaten up by the great dragon that was hovering about her; and the next day a pantomime was performed, exhibiting the battle of the dragon and the moon; and in which two or three hundred priests, bearing lanterns at the end of long sticks, dancing and capering about, sometimes over the plain, and then over chairs and tables, bore no mean part.

The dramatic representation of the eclipse of the moon is thus described by De Guignes: "A number of Chinese, placed at the distance of six feet from one another, now entered, bearing two long dragons of silk or paper painted blue, with white scales, and stuffed with lighted lamps. These two dragons, after saluting the emperor with due respect, moved up and down with great composure, when the moon suddenly made her appearance, upon which they began to run after her. The moon, however, fearlessly placed herself between them; and the two dragons, after surveying her for some time, and concluding apparently that she was too large a morsel for them to swallow, judged it prudent to retire, which they did with the same ceremony as they entered. The moon, elated with her triumph, then withdrew with prodigious gravity, a little flushed, however, with the chase which she had sustained."

It is not easy to reconcile the admission of these puerile absurdities and gross indelicacies on the stage, where regular dramas of a higher order exist, and comedians are trained up to perform them, unless it be that their thorough contempt for foreigners induces them to think any thing good enough for their entertainment. The dialogue in the regular drama is uttered in a kind of whining recitative, full of querulous cadences, which are drowned generally in a crash of trumpets, cymbals, gongs, and the kettle-drum. The passions, as in the Italian opera, are mostly expressed in song. If a fight ensues, each of the combatants sings a stanza, and then falls to, and during the combat the instruments of music keep up a most tremendous noise.

A statute is in force against females appearing on the stage, as actresses; and yet it is said that Kien-lung's mother was

at one time an actress. The parts in which females appear are performed by eunuchs and boys, the latter of whom are regularly bound apprentices to the trade. Pekin is said to have about a hundred different companies, and each company to consist of fifty persons and upwards, composed of speakers, musicians, tumblers, and jugglers, so as to suit all tastes. They live in passage-boats, in which they are conveyed from place to place. There are no regular theatres, but players are hired by the wealthy at so much by the day. They are said to be ready at any moment to perform any play that may be fixed upon, out of a list seldom short of 100. These are the sorts of plays performed before their countrymen, and not the trash which they exhibit before foreigners at the court and at the sea-port town of Canton. The translation of *An Heir in his Old Age*, by Mr Davis, is calculated to give rather a favourable opinion of the Chinese drama. It consists of five regular acts; it has plot and character; the action is simply one, and never stands still. It is deficient in wit, but not in sentiment, and the several characters are well preserved. It is, in short, a story that may commonly occur in a family, thrown into action instead of being merely told, and the catastrophe is quietly and naturally brought about.

Many of their dramas, however, are full of bustle and business, and abound with incident. They are generally representations of real life, and contain sometimes the whole life and adventures of an individual, some great sovereign, or celebrated general; a history, in fact, thrown into action, not unlike that "Lamentable tragedy, mixed full of pleasant mirth, conteyning the life of Cambyses king of Percia, from the beginning of his kingdom unto his death." The argument of a drama of this kind was found among Mr Wilkinson's papers. An aged matron and her son (the hero of the piece) being reduced to poverty, are driven to the necessity of asking alms for their support. An officer's daughter, finding them of good parentage and education, gives money to the son, and engages the mother to attend on her. The son hires himself to serve in a tea-house kept by an old woman and her daughter. A rakish young officer, liking the daughter, gains the consent of the old woman to take her into his house, but the girl rejects the offer. He then sends his servants to carry her off by force, but the new servant rescues her. The officer lays an accusation against him; he is carried before a magistrate, who orders him a flogging, and to wear the cangue or wooden collar. Not satisfied with this, the young officer sends out his people with cudgels to beat him to death. Unable, on account of the collar, to reach his mouth, they find the young girl giving him food. His hands, however, being at liberty, he lays about him on all sides, and, by a sudden whirl of his wooden ruff, the corner of it strikes the young officer on the head and kills him on the spot. The head man of the street takes him and the young woman into custody, carries them before a magistrate, who releases the young man, but takes the girl of the tea-shop into his own house, from which she is suffered to escape by his wife. The superior magistrate of the district being informed of the death of the young officer, and that the girl of the tea-house was the chief cause of it, sends an order to the inferior magistrate, who had taken her into his house, to deliver her up; but she is nowhere to be found; and, in the greatest dismay, this inferior magistrate orders his servants to go out and seize any woman they meet with and carry her before the superior magistrate. They find, in a temple, the officer's daughter first mentioned, with the old woman, who had fled from home on her father being disgraced, and all his goods and family seized. She is hurried away before the magistrate, and, in the supposition of her being the tea-house girl, sentenced to lose her head. Being carried to the place of execution at midnight, she is recognized by the old matron's son, who was among the spectators, and who, by seizing the officer's sword, attacks the executioner, and rescues the young lady; but they are speedily taken, and both ordered for execution; the truth, however, is discovered, and the magistrate who played off the trick suffers in their stead. This superior magistrate, however, falls in love with the lady, and proposes to take her for his *first* or legitimate wife, and hires the young man for his servant. The lady peremptorily refuses, upon which she is ordered to be beaten by the servants till she lies for dead, and the young man is directed to carry the body and throw it into the river. He lays her on the bank, covers her with his cloak, and goes to buy a coffin, as his last act of gratitude for one who had relieved his mother and himself in their distress. A boat approaching, and finding a woman thus bestowed, carries her off to serve the Tartar queen in her wars against the Chinese; this same people, it seems, having already carried off the old matron and the young girl of the tea-shop. Our hero returning and missing the body, falls in great distress. However, he tells his master he has obeyed his commands, who by this time has learned whose daughter he had thus cruelly treated; and, to prevent further mischief, he engages his new servant (the hero of the piece) to put to death her father, instead of which he reveals the whole to the father, and they concert together and put to death his master. The hero then flies to the wars against the Tartars; and it being the custom (or the Chinese thinking so) for the women to fight, he encounters his own mother, the young lady who relieved her, and the girl of the tea-shop, on which discovery he suffers himself to be taken prisoner by the Tartars, is brought before the queen, who, on hearing the story, sets the three Chinese women at liberty, and commits them to his care. They all return to China; they find the father of the young lady restored to his rank and honours, who bestows his daughter on the hero of the piece; and the other young woman of the tea-shop is provided for by his taking her for a second wife. By the emperor's patent he is created a great mandarin for the service he has performed, receives the suitable habit for himself and his two wives, and the congratulations of all their friends. (Macartney; Staunton; Barrow; De Guignes; *Missionary Communications* in Du Halde; Grozier, *Mém. sur les Chinois*, &c.)

Music.

As connected with the drama, the state of Chinese music may next be considered. Detestable as Europeans must find the very best of this music, such is the force of habit or prejudice, that the Chinese are as fond of their own as a Highlander is of the bagpipe. Their ancient writers ascribe to it all those extraordinary and extravagant effects of softening the manners and promoting civilization, taming wild beasts, moving rocks and stones, and, in short, performing all the wonders which have been related of the strains of Orpheus and the lyre of Amphion. The Shoo-king says, that the emperor *Chun* considered music as one of the most efficient engines of government, and a test for proving the national character. Confucius was so astounded with one of the old airs, that he could neither eat nor drink, and for three months could think of nothing else. In the book of *Odes* it is remarked, that, while the Institutes of the empire continue to be observed, and music to be cultivated, China will remain a mighty and invincible nation. And one of the early emperors has this remark: "would you conquer your enemies without bloodshed, diffuse among them songs set to tender and voluptuous melodies, to soften their minds and enervate their bodies, and then, by sending among them plenty of women, your conquest will be complete."

Dr Burney has well observed, that the more barbarous the age and the music, the more powerful its effects:

For still the less they understand,
The more they admire the slight of hand.

In China the music is still barbarous enough, whatever the people may be who can admire it. It has neither science nor system; but from a strange confused account given by Père Amiot, of the generation and true dimensions of the tones (not one word of which, as he afterwards acknowledges, he could understand), the Abbé Roussier concludes, that, like the music of the Greeks, it appears to be the remaining fragments of a complete system, belonging to a people more ancient than either of them. It will, perhaps, be safer to follow Dr Burney's conclusion, "that, from all the specimens he had seen of Chinese music (and he quotes Dr Lind, who resided some time in China, in support of his opinion), all the melodies of this nation have a very strong analogy to the old Scottish tunes;" that "the Chinese scale is very Scottish;" that "both resemble in their melodies the songs of ancient Greece;" and that, "the music of all three ought to be considered as *natural* music."

The Chinese airs are almost invariably sung in slow movements, generally plaintive, and mostly of a querulous or complaining cast; and they are always accompanied by some stringed instrument in the shape of a guitar. They make use, in singing, of so many shakes, their airs abound with so many half and quarter tones, that they are dull, drawling, and drowsy.

Their gamut consists of five natural tones, which they distinguish by five characters of the language, and two semitones; but they use neither lines nor spaces to note down their music. They however, write down in succession the characters or notes in a column, as they are played, though it does not appear that they pay any attention in marking the time, the key, the mode of expression, or the like, but acquire their airs by dint of labour and imitation. Their gamut for instrumental music is so imperfect, and the keys so inconsistent, wandering from flats to sharps, and the contrary, that they are under the necessity of being steadied and directed by a bell or cymbal. They always play, or endeavour to play, in unison, having no idea of counterpoint and parts in music. The band of Lord Macartney, on this account, afforded them no pleasure, except when it played some simple air, such as "Malbrook," or the national song of "God save the King." Some of their instruments, however, do occasionally rise to the octave in the accompaniment. The wind instruments are in general shrill, harsh, and discordant; the drums, bells, cymbals, and other pulsatory instruments, loud and jarring; and the stringed instruments meagre and jingling. The sweetest instrument is a small organ, made of unequal reeds stuck into the upper surface of a hollow cup of wood, of which there are numbers in this country, but for which Dr Burney tried in vain to adapt a scale. This we believe to be the same *tibia* which that literary coxcomb Isaac Vossius maintained to be superior to all the instruments of modern Europe.

As a favourable specimen of Chinese music, the following national song of *Moo-lee-wha* is here inserted:

This air was played by Lord Amherst's band, and delighted the Chinese more than any other.

It may be added, that the affected gravity of Chinese manners, and their unsocial life, are unfavourable to the cultivation of music, which cannot be expected to arrive even at a state of mediocrity, among a people who rarely assemble together, who take no enjoyment in the amusement of dancing, and whom the loves and the graces have not as yet condescended to visit.

Painting.

In a country where every kind of luxury is discouraged, and some of them constitute a crime, where property is so precarious as rarely to descend to three generations, and where the useful only is affected to be considered as valuable, no great progress can be looked for in the fine arts. For the same reason that their poetry is deficient in invention, imagination, and dignity of sentiment, and their music of harmony, the sister art of painting is wanting in all the requisites that are considered to be necessary to form a good picture. Indeed it could not well be otherwise, as, independently of their contracted ideas, they offend against every principle of perspective, which, with the effects produced by a proper disposition of light and shade, they affect to consider as unnatural. That it is not from want of talent that their drawings and paintings are so extravagantly outré, is sufficiently proved by the facility and accuracy with which the painters of Canton copy any picture put into their hands, whether on paper, glass, or canvass; and, so far from the Abbé Grozier's Parisian idea being true, that their best works are executed in Pekin, the very reverse is the case; all the arts, manufactures, even down to common printing, being worse executed in the capital than in any other city of the empire: and the reason is obvious enough; for the moment that a man acquires a superior reputation, he is summoned to the palace, where, within its spacious precincts, his talents must be exercised for the emperor alone. Here their arts and manufactures remain stationary, while the artists of Canton, being in the habit of copying from better models, are superior to any that the imperial palace can boast. It is all very well for a Chinese to pretend that the ancients greatly excelled the moderns in the art of painting, and to produce examples in their books of one painter having drawn on the palace walls some hawks so very natural that the little birds, afraid to approach, flew screaming away; and of another having painted a door on a wall, the deception of which was so complete, that people endeavoured to go through it: but why should the Jesuits repeat these idle stories as if they were facts? or why should we be told that the Chinese would be good sculptors if the art was not prohibited by the government? which is so far from being true, that in every temple, bridge, and burying-ground, may be seen all manner of grotesque figures of men, women, quadrupeds, and other creatures. that never existed but in the sculptor's imagination; and these we have abundantly in all manner of materials, wood, stone, metals, and baked clay. Individual objects they can paint with great accuracy; and in a composition each individual object is represented as close to the eye. Thus the leaves of trees, however distant, are distinctly represented; and objects in the back-ground are painted of the

same size with those of the same kind in the fore-ground, which they absurdly contend to be proper, because they are so in nature. It may be doubted whether the most skilful European artist can excel a Chinese in painting a bird or a reptile, an insect, a fish, or a flower; so correct is he to nature, that not one plumula of a feather, nor a single scale of a fish, escapes him, and every shade and tint of colour is minutely imitated. It is strange that a man of Pauw's sagacity should suffer his judgment to be so warped as to assign the "singular disposition of their optical organs" as the cause which prevented the Chinese from becoming good painters. As little truth is there in his assertion, that they are unable to copy from good models, without falling into their own style, and converting European eyes, ears, and noses, into those of a Chinese; they are the most servile imitators on earth. A Chinese will imitate the likeness of any object in shape, colour, and proportion. Though when left to himself he has no mind to convey the idea of distance, solidity, expression, and magnitude of objects, by fore-shortening, perspective, and a due distribution of light and shade, yet he will copy them all in a picture with scrupulous accuracy.

Sculpture.

Sculpture has been thought by some to date its improvements, if not its origin, from monumental edifices. No country can boast a greater number or variety of objects of this nature than China; but, like the rest of its edifices, they are totally destitute of the character of solidity and duration. A few monsters, or distorted forms of men and domestic animals, generally moulded in clay, are sometimes placed among the tombs, but they are wholly undeserving of notice. In cutting wood, in forming the root of a plant into the shape of human beings, quadrupeds, or monsters, they succeed better, and communicate to the features or to the action a high degree of expression; the same things occur in metal and in porcelain; but the human figure is always clothed, and a naked statue never seen. Some of the gigantic clay figures in the temples are by no means void of character and expression, and the images cut in stone, which sometimes adorn the avenues to the palaces, the gates of cities, and the parapets of bridges, monstrous as they generally are, show that, by proper encouragement and instruction, they are capable of producing something better; but they seem to be deficient in taste and feeling, and to possess no general ideas of the beauties of nature. Content with the representation of individuality, the imagination is never called into play; they servilely imitate what appears before them, with all its beauties and all its blemishes. They are deficient neither in ingenuity nor in dexterity. They engrave with a tool on copper, on silver, or on wood, as well, generally speaking, as the same kind of work can be executed in any part of Europe; and they are expert enough as lapidaries, in cutting all sorts of precious stones. They use spectacles made of crystal.

Architecture.

It is somewhat remarkable that a government so long and so firmly established, and a population so numerous and civilized, should at no period of its history have constructed a building, public or private, that could deserve the least attention or admiration for its form, solidity, or magnitude, or that could possibly resist the action of two or three centuries; such is the obstinate and inveterate adherence of this people to ancient usage, which has narrowed and confined their ideas in the construction of their dwellings to the primitive tent. Perhaps, however, the want of permanent security to private property may have operated against the construction of solid and expensive edifices, and confined them to the less durable materials of half-burnt bricks, mud, clay, and wood. This is more likely to be the case than the absurd and ridiculous reason assigned by Grozier, that the heat and moisture of the southern provinces, and the rigorous cold of the northern ones, would render buildings of marble and other stone unhealthy and scarcely habitable; and that the same reasons equally operate against a number of stories, as the second and third would not be habitable. If the Abbé Grozier had passed but a single summer's day under the roof of one of the magnificent stone buildings of Calcutta, and another under a Chinese tent, he would not have committed such nonsense to paper. From the want of windows in their houses to the street, and from the small courts behind being barricadoed by high walls, which overtop the roofs, and conceal the dwellings from adjoining courts, it may perhaps be concluded that privacy, and jealousy of their women, have been the causes that prevent the Chinese from building second and third stories to their dwelling-houses. The missionaries, however, have assigned the frequent earthquakes in the northern provinces as the cause of the lowness of the houses and slightness of the materials; as if men would speculate, over a whole empire of unparalleled extent, on a contingency which might never happen, and which, when it had happened, was confined to certain limits. The eruptions of Vesuvius have not prevented the inhabitants of Naples from building palaces, much less the Russians from rebuilding Moscow; though the distance between these two cities is not greater than that of Pekin, where earthquakes are frequent, from that of Canton, where they never happen.

These earthquakes have produced the most disastrous effects in this populous empire. The lives that have been lost are reckoned in Chinese history by hundreds of thousands, especially under the Mongoos dynasty. This might lead to a suspicion of exaggeration, as famines, earthquakes, and inundations, are considered by the Chinese as the scourges inflicted by heaven on the people, to show its dislike to a sovereign whom it disapproves, did not the accounts of more recent earthquakes, given by the missionaries, who were eye-witnesses of their tremendous effects, correspond with those recorded in Chinese history. It is stated by Père Mailla, that, in 1679, in the reign of Kaung-hee, more than 300,000 inhabitants of Pekin were buried under the ruins of the houses thrown down by an earthquake; that at the same time above 30,000 persons perished in the city of Tong-tchoo. The statements, however, of the missionaries, are vague and discordant. Père Couplet says, *Sub decimam horam matutinam, regiam urbem et loca vicina tam horribilis terræ motus concussit, ut innumerá palatia, deorum fana, turres et urbis mœnia corruerint; et sub ruinis sepulta quadraginta hominum millia.* Again, in 1730, in the reign of Yong-tchin, a violent earthquake shook the capital to its foundations, and 100,000 of its inhabitants were crushed to death. The earth opened in various places, black volumes of smoke issued forth, and left behind large pools of water. The city of Pekin is represented as affording a horrible spectacle; its walls, its palaces, the public buildings, two of the Jesuits' churches, and a multitude of dwelling-houses, were wholly or in part thrown down. The palace of the emperor, more solid than any other edifice, was greatly injured; that of Yuen-min-yuen was scarcely reparable. Of the 100,000 inhabitants contained in the adjoining village of Hai-tien, 20,000 are stated to have perished. The imperial family betook themselves to their barges in the canals within the precincts of the palace. The emperor distributed many millions of money to the sufferers, and gave the Jesuits one thousand ounces of silver towards the expense of repairing their churches.

If earthquakes were to throw down the tall and ill-built brick pagodas of seven and nine stories in height, there would be nothing surprising; yet these appear to stand

China. the shocks, and many of them are evidently among the oldest buildings in China. These, and the temples of Fo and Tao-tse, are among the most striking buildings of the country. The want of a national or state religion will best explain the want of those magnificent edifices in China, that almost every other civilized nation has reared to the objects of divine worship. Some of their bridges are light, and sufficiently pretty in their appearance; but they are generally slight and faulty in their construction. They consist of every possible variety of form. Their monuments to the memory of the dead are still more various than their bridges, but they are poor in design and bad in execution. Wooden pillars forming a triple gateway, roofed over, and painted, gilt, and varnished, are among the most striking objects that catch the eye of a stranger. They are monuments erected at the public expense, in streets or by the sides of highways, to commemorate some celebrated warrior, some ancient mandarin, or some antiquated virgin who had withstood temptation, and never swerved from the strict rules of decorum. To such a one will probably be inscribed, in letters of gold, " Honour granted by the emperor—to icy coldness, hard frost." But these *pei-loos* have little permanency. The mandarin to whom the emperor's order is addressed for erecting it, employs a carpenter, contracts for building the edifice as cheaply as he can, and pockets the rest of the money. The emperor's object is answered by publishing the edict in the National Gazette. It is handed down to posterity in the great history of the empire, whilst the monument itself in a few years is consumed by the dry-rot, and is seen no more.

Superior as the temples and palaces of the Hindus and Mahommedans in India and Persia, and indeed throughout Asia, are to those of the Chinese, the dwellings of the latter are infinitely more comfortable in every respect than those of the former. Their stoves for warming the apartments and for cooking, their beds and furniture, bespeak a degree of refinement and comfort unknown to other oriental nations; but the great characteristic difference is, that the Chinese sit on chairs, eat off tables, burn wax candles, and cover the whole body with clothing.

Naval architecture. Their naval architecture wears the stamp of great antiquity, and is exceedingly grotesque. They have, in fact, made little progress in maritime navigation, from the inveterate dislike of the government to all foreign intercourse, and to all innovation. The very same kind of vessels as those described by Marco Polo at the port nearest to Pekin, in the thirteenth century, were found without variation by Lord Macartney, five hundred years afterwards, and accurate to the Italian's description, even to the number of compartments into which the hold of each vessel was divided. They had anchors of wood, and ropes and sails of bamboo. The boats and barges for internal commerce and communication are very varied, generally commodious, especially the passage-boats on the grand canal, and all of them suited to the depth and velocity of the stream, and the width of the locks and flood-gates of the respective canals and rivers which they are intended to navigate. These vessels are so numerous as almost to supersede the necessity of land-carriage; and the most common and convenient mode of travelling in China is in barges, which are generally provided with cabins for sleeping, and a kitchen and utensils for cooking victuals. Their military navy is unworthy of the name. It consists of a flotilla, whose principal occupation is that of conveying soldiers from place to place as they may be wanted, and looking after pirates and smugglers. (Du Halde's *History of China;* Barrow's *Travels in China;* Grozier, De Guignes, &c.)

The state of their military architecture and military science is equally rude and imperfect. There is nothing, in fact, from the celebrated wall on the side of Northern and Western Tartary, to the mouth of the Bocca Tigris near Canton, that merits the name of a fortress. They are all of the same construction, being mounds of earth heaped into the shape of a wall, and cased on each side with bricks, and flanked with square towers at bowshot distance; and with walls of this description all their cities are surrounded. China. Military architecture.

The best defences of China are its great distance from any civilized country; its rugged mountains and sandy deserts on one side, and a stormy sea, whose navigation is but little known, on the other. In its military strength it can place little or no confidence; a fact which has frequently been proved by the successful incursions of the Tartars, who have twice since the Christian era conquered the whole country, and changed the ruling dynasty. Nor is it to be expected that a race like the Chinese, in the most servile condition, and subjected to the greatest humiliations, can make good soldiers. Military and defences.

It has been supposed, from their skill in fire-works, and from the frequent mention of them in ancient books, that the deflagrating power of nitre, sulphur, and other ingredients, was well known to them; but it is pretty evident that they had but an imperfect, if any knowledge of cannon or muskets, before the arrival of European missionaries in the capital. We may form some notion of the mode of fighting of the Tartars and the Chinese about the Christian era, from the memoir of a general officer, presented to the sovereign when about to make war on the Tartars.

" The manner," this general says, " in which the Tartars carry on war is very different from ours. To mount up and descend the steepest mountains with astonishing rapidity; to swim deep and rapid rivers; to brave storms of wind and rain, hunger and thirst; to make forced marches, and overleap all impediments, training their horses to tread in the narrowest paths; expert in the use of the bow and arrow, they are always sure of their aim—such are the Tartars. They attack, retreat, rally, with a promptitude and facility peculiar to themselves. In the gorges of the mountains, and in the ravines and deep defiles, they will always have the advantage over us; but on the plains, where our chariots can perform their evolutions, our cavalry will always beat theirs. Their bows have not the strength of ours, their spears are not so long, and their arms and arrows are inferior in quality to ours. To stand firm, to come to close quarters, to handle the pike, to present a front, to cut their way when surrounded, are the proper manœuvres of our troops, of which the Tartars are ignorant, and against which they can oppose no successful resistance. In such situations, with equal numbers, our forces are as five, when the Tartars are but as three." (*Hist. Gén. de la Chine.*)

The first mention of anything like fire-arms, and that is but an equivocal one, is in the year 1219, when Gengis-khan was penetrating the provinces of China. It is stated that the Chinese, from the turrets of the walls of Tsao-yong, played their machines called *pao*, the present name of guns, by which they killed great numbers at every stroke. Again, when Ogdai-khan laid siege to Lo-yang, the Chinese commandant Kiang-chin invented a kind of *pao*, which hurled large stones to the distance of one hundred paces, with such accuracy as to strike any point that might be desired. But another passage is more to the purpose. The Tartars are said to have breached an angle of the wall, by employing more than a hundred machines, consisting of tubes, each made of thirteen laths of bamboo; that the Chinese repaired these breaches with wood, straw mixed with horse-dung, &c., which the Tartars set on fire with their *ho-pao*, or fire-tubes; and immediately

afterwards we find these *ho-pao* called *Tchen-tien-ley*, or heaven-shaking thunder; and it is further stated that a certain substance put into them, when set on fire, explodes like a thunder-clap, loud enough to be heard at the distance of a hundred *ley*, or thirty miles. This description, and that of the effects produced, leave no doubt of these bamboo staves, hooped together, being the first attempt in China at the use of cannon, to which succeeded probably those of plates of malleable iron, also hooped together, several of which kind have been found in India, and also seen by Bell, lying in heaps, within the walls of a city near the great wall.

In 1453 we find mention made of chariots of war, carrying cannon in their fronts; but it is probable they knew very little of the use of them; for when Chin-tsing, in 1608, made war upon the Tartars on the northern frontier, and was defeated, the Portuguese at Macao, availing themselves of the panic into which the Chinese were thrown, made an offer of assistance with a party of artillery. A Jesuit was dispatched from the capital to hasten the new auxiliaries. The party consisted of two hundred Portuguese, and as many Chinese trained and exercised in the European manner, and they were commanded by two Portuguese captains, Pierre Cordier and Antoine Rodriguez del Capo. They were feasted and treated with distinguished honours on their passage to the capital, where they were well received and generally admired, except in the cut of their jackets, which, according to Chinese notions, were too scanty to be elegant. This admiration, however, soon ceased, and in a few days they were sent back to Macao. It is stated by one of the missionaries, that this was owing to a Portuguese and four Chinese being killed in firing the guns. That the Jesuit Verbiest taught them how to cast cannon there can be no doubt, for the president of the tribunal of rites thanks the missionaries for this signal service; and the matchlocks now in use by the Chinese troops are nothing more than the old Portuguese matchlock.

The Tartars are soldiers by profession, mostly cavalry, and their arms the bow and a broad simitar, which they wear on the left side, with the point forwards, and which they draw by carrying the right hand behind them, in order, they say, that their adversary may not cut the arm when in the act of drawing. They are arranged under eight banners, distinguished by different colours. The Chinese soldiers are for the most part a sort of militia, enrolled for the defence of the extended frontier, guards to the city gates, and the military posts placed at certain distances along the roads, rivers, and canals. All expresses are forwarded from post to post by the soldiers. Vast multitudes are employed to assist the civil magistracy, and act in the cities as police-officers. Their dress and appearance are most unmilitary, better suited for the stage than the field of battle; their paper helmets, wadded gowns, quilted petticoats, and clumsy satin boots, are but ill adapted for the purpose of war. Indeed, unless it be to quell an insurrection, or to pursue bands of robbers, the Chinese military are rarely called away from their pacific employments. There was some anxiety, on the return of Lord Amherst through the country, that the military should put on an imposing appearance. "Through the whole route," says the emperor, "take care that the soldiers have their armour fresh and shining, and their weapons disposed in a commanding style, and that an attitude be maintained at once formidable and dignified."

The people are all enrolled for service, when called upon, from a certain age. A father of a family, having a certain number of children, is exempt from service; an only son, and a son who supports his parents, are both exempt. Great distinctions are shown to those who fall in battle. The body of an officer is burnt, and his ashes, with his armour and a suitable eulogium, sent to his friends; the bow and sabre of a common soldier slain in fight are sent to his family; rewards are distributed, and honourable mention made of the deceased in the Pekin Gazette.

All the military of the empire are under the management of their proper tribunal or board at Pekin, the power of which, however, is jealously checked by a dependence on some of the others,—as the Board of Revenue which supplies the funds, and the Board of Public Works which supplies the *materiel* of the army. The total number of the Tartar troops is estimated to be about 80,000 men; besides which there is the local militia spread through the provinces, which may amount to about 600,000. By far the greater portion of the latter are fixed to their native districts, and are chiefly occupied in cultivating the land, or in following some other private pursuit. From such materials the army of China cannot be otherwise than in a very inefficient state. That overwhelming superiority which the empire possesses over the petty and barbarous states on its frontiers has prevented aggressions on it, but has likewise precluded the practice and experience necessary to make good soldiers.

The Chinese seem to possess no knowledge of the pure, speculative, and abstract science of mathematics. Their knowledge of arithmetic and geometry is bounded by mere practical rules. Their numerical notation is marked down by symbols of the language, as that of the Greeks and the Romans was by letters of the alphabet; and, like them, the Chinese symbols want that value in position which the Arabic numbers possess. The common operations of arithmetic are generally performed by a few balls strung on wires, somewhat resembling the Roman abacus, and sometimes by the joints of the fingers. The measure of quantity is usually determined, by reducing all surfaces and sides to the dimensions of squares or cubes; and with those few practical operations they contrive to manage all the common purposes of life.

Yet the Chinese have been represented by some of the French missionaries as profound astronomers at a time when all Europe was in a state of barbarism; as being able to calculate the recurrence of eclipses; to adjust the irregular motions of the sun and moon; to measure the distances of the planets, and so forth. The ridiculous ceremonies observed by the great officers of state when eclipses happen, furnish, it is true, no proof against the knowledge of their causes. A government established on ancient customs cannot afford to lop off any of its props; and the foretelling of eclipses, the frightening away of the dragon that would devour the sun or moon, the favourable or unfavourable omens of the heavenly appearances, are so many engines for keeping the ignorant in awe. The Imperial Calendar is an admirable coadjutor of the Imperial Gazette. But when we find, from their own annals, and from the report of the earliest travellers, that foreigners have had the superintendence of the astronomical part of this almanac; and that, from the defective knowledge of these foreign astronomers, and the occasional want of them altogether, the national calendar, as declared by one of their emperors, had undergone no less than seventy-two revisions, it may safely be concluded that the Chinese know very little of the matter. M. Fréret says he had in his possession the copy of a celestial chart, constructed in China about the sixth century of the Christian era, on which were inserted 1460 stars in their proper positions, at least sufficiently near to be recognised; but this may have been made mechanically, and perhaps by a foreigner. It is recorded in their annals, that in 718 of the Christian era, an Indian astronomer of the name of *Koo-tan*, having brought from the west a treatise on astronomy, was employed at court

China.

to translate it into the Chinese language; and they also mention that Kublai-khan encouraged learned men to remain in China, and that under his reign an Arab astronomer was employed in rectifying the calendar, and constructing astronomical instruments. Since that time, Armenians, Bucharians, Hindus, Arabs, and Christians, have presided over the board charged with the construction of the National Almanac, in which the native Chinese took no other part than that of assigning the lucky and unlucky days, what was to be done and what abstained from on those days. When Lord Macartney was in Pekin, a Portuguese, who called himself Bishop of Pekin, a person of no great skill in mathematical knowledge, presided over this board. Indeed, the state in which their calendar was found when Adam Schaal, one of the earliest Jesuits, made his way to Pekin, sufficiently proves their ignorance of astronomical calculations, an intercalary month having been introduced into the wrong year. On making them acquainted with this blunder, all the departments of the state, ordinary and extraordinary, were summoned to sit in judgment on the good father's report, which they voted to be erroneous, and that the ancient system should be continued. They kept, however, the learned Jesuit at court, and quietly allowed him to set them right. The emperor Kaung-hee, who seems to have entertained no high opinion of his Chinese subjects, brought the Chinese president of the board of astronomy to trial because he could not calculate the length of shadow which a gnomon would throw, but which was immediately done by Father Verbiest. This intelligent Tartar put himself under the tuition of the Jesuits, who made for him a quadrant, translated into the Chinese language a set of logarithm tables, which were printed, and a copy of which is now in the library of the Royal Society of London; a very beautiful specimen of Chinese typography. Kaung-hee carried these tables and his quadrant suspended from his girdle, and, when in Tartary, is said to have constantly amused himself in taking angles, and measuring the height of mountains.

The Chinese system, if system it can be called, of astronomy, resembles so closely that which remains of the Hindus, that both must have been derived from the same source. The period or cycle of sixty years, by which their chronology is regulated—the period of 10,800 years, observed by the Tao-tse, which is the sum of the first three Hindu ages, with their intermediate periods—the division of the zodiac into twelve signs, and also into twenty-eight constellations, or habitations of the moon, corresponding with the twenty-eight Hindu nacshatras—are so many proofs of a common origin; and both may perhaps have derived the remains of this science from some third nation, more ancient than either; as the little which both nations do possess appears to be the remains rather than the elements of the science.

The system of policy which discouraged all intercourse with strangers, which set no value on foreign commerce and navigation, and which cultivated no language but that of the country, which was unintelligible to other nations, must necessarily have kept the people of China in ignorance of all the rest of the world. China was to them, in fact, the whole world. It appears, however, that at a very remote period they had intercourse with Pegu, Siam, Malacca, Hindustan, and several of the Asiatic islands. Two centuries before the Christian era, they had a knowledge of the upper regions of Tartary; and one of their travellers gives an account of an inland sea, into which the rivers running to the westward were received, which could be no other than the Caspian. The great islands of Borneo, Java, Sumatra, and Ceylon, are names easily recognized in their annals, on which great numbers of Chinese are still found, retaining their original language, manners, and government. Captain Sayer, of his Majesty's ship Leda, on ascending a river of the western coast of Borneo, came unexpectedly on a colony of Chinese in the interior, consisting of not less than 200,000 or 300,000 persons, all united under one chief or captain; and Sir Thomas Raffles says, that near the same place, it has been calculated that the number of Chinese employed in the gold mines alone amounts to 32,000 working men.

Their knowledge, however, of their immediate neighbours was very limited and imperfect. By the aid of practical geometry, they had a tolerable notion of their own country. Père Mailla asserts, that on comparing an ancient chart of China, said to be copied out of the *Shoo-king*, with the actual survey made by his brother Jesuits and himself, and which took them ten years to complete, they found the limits and the positions of the provinces, the courses of the rivers, and the direction of the mountains, pretty nearly to accord; but the proportions of the objects to each other, and to the whole, were not in the least observed. He further observes, that they saw and gazed with astonishment and admiration at the chasms which the emperor Yu caused to be cut through solid mountains, to open new channels for the waters of the Yellow River. Some, however, will be apt to conclude that it was the water itself, and not the emperor Yu, which opened these channels.

Of natural and experimental philosophy, they know only what the Jesuits taught them, and that appears not to be much. Of clock-making, dialling, optics, and electricity, they know nothing; of hydrostatics and hydraulics, very little. They raised water by a machine resembling the Persian wheel, and by a large wheel, with bamboo tubes fixed obliquely on its rim; but they were ignorant even of the principle of the common pump. The use of most of the mechanical powers is known to savages; but the most commodious and effective application of them was not known to the Chinese. In most cases manual strength supplied the place of mechanical power. When Mr Barrow, in delivering the presents to the emperor Kien-lung, failed in making him comprehend the use of the mechanical powers from a complete set of models, the old man observed, that they might serve as playthings for his grandchildren.

State of the liberal professions.

The nature of their own language, their universal ignorance of any other, and their pertinacious resistance to all intercourse with foreigners, may explain the low ebb of the sciences and liberal professions in China. The maxims of the sovereigns and sages of antiquity, the rites and ceremonies and duties required by the civil and religious institutions of the empire, the laws and customs, are the points of knowledge which lead to wealth, power, and distinction in the state. As there is no established religion, so none is paid or preferred by the government for instructing the people. As there is no pleading in criminal or civil suits, so there are none who act as attorneys or advocates; and the practice of physic is attended with too little either of honour or emolument to excite emulation in men of rank and ability in the pursuit of it, and is generally in the hands of the sectarian priests of Fo and Tao-tsé, or of low vulgar quacks. Without the least knowledge of anatomy or surgery, they can know little of the animal economy. The seat of the disease they pretend to discover by the quackery of the pulse, by the eye, the nose, the tongue, the ears, and the voice. When this is ascertained, they prescribe their vomits, purges, febrifuges, &c. extracted from the three kingdoms of nature, of which mercury, antimony, rhubarb, and ginseng, constitute no inconsiderable part. Of ginseng alone they profess to have no less than seventy-seven preparations. Their sur-

gery consists chiefly in acupunctuation and shampooing, and it is practised chiefly by the barbers. There are certain persons whose occupation is to discover whether those who may be found dead have died a natural death or by violence, whether by their own means or that of others; and the verdict of the criminal court is often grounded on the decision of these quacks.

The emperor Kaung-hee soon convinced himself that several of the Jesuits were better skilled in medicine than his own physician. At first, however, he had some scruples, upon being attacked by a fever, of following their advice. Three of the first physicians to the court dissuaded him from taking a medicine of whose qualities they professed themselves ignorant, and advised him to let the disease go on, that they might discover its true character. The emperor, however, at last took the Peruvian bark which the Jesuits had prescribed, and soon recovered; but it is said in the *General History*, that several officers who had similar fevers were first ordered to take the bark, and finding it at least harmless, he then ventured upon it himself. As ignorance is a crime in the eyes of the ignorant, it is more especially so at the court of China, and made capital in those to whom the life of the sovereign is intrusted. The three physicians were, therefore, delivered over to the criminal court, who condemned them to death; but Kaung-hee mitigated the punishment to that of exile, and rewarded the Jesuits with a house in Pekin, and contributed largely towards the building of a church.

Kaung-hee was a man of great humour, and used frequently to joke with the missionaries respecting their religion and the customs of their country. One day he asked Mezzabarba, the pope's legate, if it was the custom in Europe to condemn a man to death without sufficient proof of his guilt; and being answered in the negative,—" One cannot," says the emperor, " attach too great a value to the life of man;" and turning to his body physician, and ordering him to approach, " Here," continues he, " is a much more formidable person than myself. I can only put a man to death on legal proof of guilt; but this fellow can dispatch whomsoever he pleases without the form of trial."

Whoever may be curious to see the quackery of the pulse detailed, without a complete knowledge of which a physician would gain no reputation in China, may find a translation of the doctrine in the collection of Du Halde.

The Chinese are subject to a species of contagious leprosy, which their physicians cannot cure, and which the law ordains to be a legitimate cause of divorce, as the only means to stop its progress. The itch is most prevalent, and cutaneous disorders of various kinds are very common; but they have escaped the plague, more, as Pauw thinks, by constant ventilation, by burning sandal-wood dust, and other odoriferous woods, by the abundant use of musk and various strong scented drugs, than by any attention to cleanliness. Perhaps, also, the universal smoking of tobacco may have contributed to save them from the horrors of the plague. (*Hist. Gén. de la Chine*, par Du Halde.)

Though little progress has been made in any of the liberal arts or abstract sciences, and little as they are likely to advance under a system of government which interdicts all intercourse with foreign nations, the arts which necessity demands, which add to the conveniences and increase the comforts of a civilized state of society, seem to have flourished at a very early period of their history; and many of them have been brought to a degree of perfection which is still unequalled by the most polished nations of Europe. Whatever depends on mere imitation and manual dexterity, can be executed as well and as neatly by a Chinese, as by the most skilful artists of the western world; and some of them in a style of very superior excellence. No people, for example, have carried the art of dyeing, or of extracting dyeing materials from so great a variety of animal, mineral, and vegetable substances, as the Chinese have done; and this merely from a practical knowledge of chemical affinities, without troubling themselves with theories derived from scientific principles. In like manner practice has taught them how to detect the exact proportion of alloy that may be mixed with gold and silver, and how to separate it. We import from China their native cinnabar; but our vermilion, extracted from it, is not to be compared with theirs for brilliancy and deepness of colour, which is supposed to be given to it by long and patient trituration under water. Again, the beautiful blues on their porcelain are more transparent, deep, and vivid, than the same blues applied to our pottery-ware; yet we supply the Chinese with the same cobalt frits from which our own colours are extracted. It has been supposed that the greater or less brilliancy of the colours used for painting porcelain depends more on the nature of the glaze on which they are laid, than on their own intrinsic merits. Here then we have something still to learn from the Chinese. The biscuit of their porcelain, too, is much superior in whiteness, hardness, and transparency, to any which has been made in Europe. The Swansea porcelain comes the nearest to it in these respects, which is supposed to be owing in some degree to a proportion of magnesian earth being mixed with the aluminous and silicious ingredients. In form and decoration, which depend on a taste and feeling which the Chinese are strangers to, we far surpass them.

In the cutting of ivory into fans, baskets, pagodas, nests of nine or more hollow movable balls, one within the other, beautifully carved, the artists of Europe cannot pretend to vie with the Chinese; yet it does not appear that they practise any other means than that of working in water with small saws. As little can Europeans pretend to rival their large horn lanterns, of several feet in diameter, perfectly transparent in every part, without a flaw or opaque spot, and without a seam; yet a small portable stove or furnace, an iron boiler, and a pair of common pincers, are all the tools that are required for the manufacture of those extraordinary machines. In silver fillagree they are at least equal to the Hindus, and their lacquered cabinets and other articles are excelled only in Japan. They are not less expert in cutting tortoise-shell and mother of pearl, and all kinds of gems and stones. They have a method of ornamenting their cabinet wares, tea-chests, and other articles, with spangles laid on with the black varnish in the shape of plants, birds, insects, &c., exhibiting varied iridescent colours, appearing like metallic scales that have undergone the process of heat; but they are nothing more than the thin lamina of a particular species of shell (*Helix*), which they have a method of separating by boiling, as they pretend, for the space of half a moon. In all the metals they work with neatness; and if they make not a lock or a hinge that an English artist would look at, it is only because a Chinese would not pay the price of a good one. Their white copper is a metal, or a mixture of metals, unknown in Europe; and though we think that we have ascertained the component parts of the famous gong to be copper, tin, and bismuth, we are yet unable to make a Chinese gong. In works of the loom, and especially in the manufacture of silk and satin cloths, we cannot pretend to cope with them; and their silken twisted cords, tassels, and all kinds of embroidery, in general the labour of females, are extremely beautiful. In the variety of gums, spices, and perfumes, they excel the rest of the world. Our artists can attest the excellence of their ink, and their paper and printing may challenge those of Europe. Many other branches of the mechani-

cal arts might be enumerated, in which the Chinese may consider themselves as second to none; but those already mentioned are sufficient to exemplify their skill in this respect. There are no manufactories carried on by machinery, or upon a great scale. Generally speaking, each individual in the country spins, weaves, and dyes his own web. It would appear, however, from some regulations laid down in the *Leu-lee*, that of porcelain, silks, satins, and certain other articles, government is its own manufacturer. The manufactories of porcelain and the coarser kinds of pottery, for the sake of the coal, are mostly in Kiang-see; and the village of Kin-te-chin, it is said, contains nearly a million of people, all of them engaged in the potteries.

Not the least remarkable circumstance connected with this remarkable country is the immense population that it contains. It was usual to doubt the accuracy of the accounts commonly given by the Chinese on this subject, but as the country has become more known, the nearer do these statements seem to be to the truth. "I think," says Sir John Bowring, "our greater knowledge of the country increases the evidence in favour of the approximate correctness of the official document, and that we may with tolerable safety estimate the present population of the Chinese empire as between 350,000,000 and 400,000,000 of human beings." The following is the population of China according to the last official census—that of 1812:—

Provinces.	Area in square Miles.	Average population to sq. mile.	Total population.
Chihli	58,949	475	27,990,871
Shantung	65,104	444	28,958,764
Shonsi	53,268	850	14,004,210
Honan	65,404	420	23,037,171
Kiangsu	44,500	850	38,843,501
Ngonhwui	48,461	705	34,168,059
Kiongsi	72,176	320	33,046,999
Chekiang	39,150	671	26,256,784
Fokien	53,480	276	14,777,410
Hupeh	70,450	389	27,370,098
Hunan	74,320	251	18,652,507
Shensi	67,400	153	10,207,256
Konsuh	86,608	175	15,193,125
Sz'chuen	166,800	128	21,435,678
Kwontung	79,456	241	19,174,030
Kwongsi	78,250	93	7,313,895
Kweichan	64,554	82	5,288,219
Yunnan	107,969	51	5,561,320
Shingking	...	...	2,167,286
Total	1,297,999	6,574	362,447,183

The following is a statement of some of the most trustworthy censuses of China, taken at different periods:—

Authorities.	Date of Census.	Population.
Chinese Repository	1711	28,605,716
Grozier, De Guignes	1736	125,046,245
,, ,,	1743	157,343,975
Chinese Repository	1753	103,050,060
Yih-tung-chi, a Chinese work	1760	143,125,225
De Guignes	1760	203,916,477
,,	1761	205,293,053
Allerstein, Grozier, De Guignes	1762	198,214,553
Chinese Repository, vol. i.	1790	155,249,897
Dr Morrison	1792	307,467,400
Lord Macartney	1792	333,000,000
Chinese Repository, vol. i., p. 359	1812	362,467,183

The four censuses which deserve the most credit, so far as the sources from which they are obtained are concerned, are those of 1711, 1753, 1792, and 1812. They show the following rates of increase:—

From 1711 to 1753 the population increased 74,222,602, which was an annual advance of 1,764,824 inhabitants, or a little more than six per cent. per annum for 42 years. This high rate of increase, however, it must be remembered, arises in some measure from the more thorough subjugation of the S. and W. at the later date when the Manchoos could safely enrol large districts, which in 1711 they would not have been allowed to enter for such a purpose. From 1753 to 1792 the increase was 104,636,882, or an annual advance of 2,682,997 inhabitants, or about two and a half per cent. per annum for thirty-nine years. During this period the country enjoyed almost uninterrupted peace under the sway of Kien-lung, and the unsettled regions of the S. and W. rapidly filled up.

From 1792 to 1812 the increase was 54,126,679, or an annual advance of 2,706,333,—not quite one per cent. per annum for twenty years. At the same rate the present population would amount to over four hundred and fifty millions; but from the great numbers that have left the country since the last census, as well as from the internal disturbances that have recently taken place, it is probable that they do not nearly amount to that sum. They have overflowed the bounds of their possessions on all sides, especially in Manchooria, Mongolia, Ili, and towards Thibet, while the emigration towards the Indian Archipelago and other places has also been very large.

The constant flow of emigration from China, contrasted with the complete absence of immigration into China, is striking evidence of the redundancy of the population. In the kingdom of Siam it is estimated that there are at least a million and a half of Chinese, of which 200,000 are in the capital (Bangkok). In Java there are 136,000 of them. Cochin-China teems with Chinese; and they abound in all the islands of the Indian Archipelago. Multitudes go to Australia, the Philippines, the Sandwich Islands, California, and the western coast of Central and Southern America. The emigration to the British West Indies has been considerable; to the Havannah greater still. The annual arrivals in Singapore are estimated at an average of 10,000, and about 2000 are said annually to return to China. Besides this enormous maritime emigration, a considerable inland efflux of Chinese takes place towards Manchooria and Thibet; and it may be added, that the large and fertile islands of Formosa and Hainan have been to a great extent won from the aborigines by successive inroads of Chinese settlers. Yet this perpetual outflowing of people seems in no respect to diminish the number of those who are left behind. Few Chinamen leave their country without a fixed purpose to return to worship in the ancestral hall, to bring sacrifices to the tombs of their fathers; but it may be doubted if one in ten revisits his native land. The loss of life from disease, from shipwreck, and other casualties, amounts to a frightful per-centage on those who emigrate.

The prevalence of infanticide in China is also adduced by some as a proof of the extreme populousness of the empire. That this revolting system is carried on to such an extent as to have any considerable effect in diminishing the numbers of the people, or that it is viewed with indifference by government, as tending to keep down the population, we are inclined to doubt; though it is very probable that much of it is the result of poverty. This practice is not taught or enjoined by any religious system in China, nor do they expect to reap any spiritual advantage from it; and females being the objects of it, it is likely that the parents wish to save themselves the trouble and expense of bringing up one who is likely to cost more than she will ever bring on being sold out in marriage. Boys, on the contrary, are likely to repay by their labour the care and expense bestowed on them, and contribute to the building up of the family name and fortunes.

The statements of Dr Morrison were taken by him from Chinese works. That of Lord Macartney, who was ambassador to China from England, rests on Chinese authority. The census of 1812, as given above, was considered by

Drs Morrison and Bridgman, who must be ranked among the highest authorities, as "the most accurate that has yet been given of the population."

The fact is, that the censuses, as that of 1812 and others, taken by the Chinese government, were not intended for the public eye; they were taken, moreover, under circumstances which would greatly tend to render them too small rather than too large, for the people of China have ever endeavoured, as the people now do and have done in all Spanish countries, to cause as small a number to be registered as possible, hoping thereby to escape the contribution that would be levied on them by the government. Dr Morrison says,—"We know from several authorities that the people are in the habit of diminishing rather than increasing their numbers in their reports to government;" and one reason for doing so is, that the local authorities may pocket the difference in the taxes assessed for collection in their districts. (Williams's *Middle Kingdom.*)

There can be little doubt that the present redundancy of the population renders dependence for support on the produce of the country very precarious, and frequently induces much suffering from an inadequate supply of food. Though extraordinary harvests may have enabled the Chinese to export rice to foreign countries, yet of late the importations from foreign countries have been very large; and notwithstanding this, famine has committed dreadful ravages, the provisions of the imperial granaries having been wholly inadequate to provide for the public wants. The evil consequences resulting from an over-abundant population are experienced in one or another part of the kingdom almost every year,—drought, inundations, locusts, mildews, or other natural causes, producing a deficiency in the crops, give rise to frequent insurrections and disturbances. The anxiety of the government to provide stores of food for the necessities of the people in times of scarcity, shows rather the fear of the disastrous results usually following a short crop, such as the gathering of clamorous crowds of starving poor, and the consequent increase of banditti and disorganization of society, than any peculiar care of the rulers for their subjects.

It has been supposed that nearly a tenth of the population live by the fisheries, thus affording evidence not only that the land is cultivated to the greatest possible extent, but that it is insufficient to supply the necessities of the overflowing population; for the pursuit of agriculture is in high esteem among the Chinese, the husbandman standing next in rank to the literary man in the social hierarchy. The immense number of persons that live continually in boats,—that are born, marry, rear families, and die on the water,—shows to what an extent the land is crowded, and how inadequate it is to maintain the cumberers of the soil. In the city of Canton alone it is estimated that 300,000 persons dwell upon the surface of the river, the boats extending for several miles, sometimes twenty or thirty deep; while the wants of the people are supplied by ambulatory salesmen, who wend their way by every accessible passage. Some of these boats are finely decorated, and used for every purpose of license and festivity,—for theatres, concerts, feasts, gambling, &c.; others are employed in conveying goods and passengers, and are in a state of constant activity; and others are moored, and their owners engaged as servants or labourers on shore. Indeed, their pursuits are probably nearly as various as those of the land population. But besides these, many of the Chinese dwell on artificial islands which float upon the lakes. These are formed by the binding together of rafters on which they raise houses and gardens. There they have everything needful for the supply of their daily wants—their poultry and vegetables for use, their flowers and scrolls for ornament, and their household gods for protection and worship.

While so many elements of vitality are in a state of activity for the reproduction and sustenance of the human race, there is probably no part of the world in which the harvests of mortality are more sweeping and destructive than in China. Multitudes perish absolutely from want of the means of subsistence; inundations destroy towns and villages, with their inhabitants; and typhoons or hurricanes, which visit the coast occasionally, cause immense loss of life. The late civil wars in China must have led to the loss of millions of lives. The sentiment of dishonour attached to the extinction of a race by the want of descendants is general among the Chinese, arising from the reverential services which descendants pay to their ancestors. The Chinese moralists set it down as a law, that if a wife give no children to her husband, she is bound by every tie of duty to encourage and to patronize a concubine through whom his name may be preserved, and provision made that when he leaves the world honours will be paid to his manes. Generally the wife willingly coincides with the husband in introducing into the household any number of concubines he may be able to maintain; and the child of a concubine is bound to pay higher respect to the first wife than to its own mother. The domestic affections of the Chinese are strong; and on the whole the social arrangements must be considered friendly to an augmentation of the human race. Parents are generally very fond and proud of their children, and the children are obedient to their parents.

The marriage of their children is one of the great concerns of families. Scarcely is a child born in the higher ranks of life ere the question of its future espousal becomes a frequent topic of discussion. There is a large body of professional match-makers, whose business it is to put all the preliminary arrangements in train, to settle questions of dowry, to accommodate differences, and report on the *pros* and *cons* of suggested alliances. There being no hereditary honours in China, except those which reckon upwards from the distinguished son to the father, grandfather, and the whole line of ancestry, which may be ennobled by the literary or martial genius of a descendant, the distinctions of caste are unknown, and a successful student, even of the lowest origin, would be deemed a fit match for the most opulent and distinguished female in the community. The severe law which prohibits marriages within certain degrees of affinity tends to make marriages more prolific, and to produce a healthier race of children. So strong is the objection to the marriage of blood relations, that a man and a woman of the same *sing* or family-name cannot lawfully wed. The proportion of unmarried to married people is exceedingly small. To promote marriages seems everybody's affair. Matches and betrothings naturally enough occupy the attention of the young, but not less that of the middle-aged and the old. A marriage is the great event in the life of a man or woman, and in China is associated with more of preliminary negotiations, ceremonials at different steps of the negotiations, written correspondence, visitings, protocols, and conventions, than in any other part of the world. (Sir John Bowring; Williams's *Middle Kingdom.*)

Classes of society.

The constituent parts of the population of China were anciently considered to consist of four classes: the *tsé*, or learned, who governed and instructed the rest; the *nung*, or agriculturists, who provided food and materials for clothing the rest; the *kung*, artizan or manufacturer, who clothed, and built, and furnished houses for the rest; and the *shang*, who distributed and exchanged the productions of the other two among all the classes of society. But nothing like a division into *castes* ever appeared in China. On the contrary, every encouragement is held out for the children of the three inferior classes to aspire to the first.

The numbers of the *tsé*, or officers and literary men, consisting of the members of the several boards, governors of provinces and cities, judges, treasurers, collectors, commissaries, inspectors, and the like, with an enormous list of subaltern officers and literati, cannot, according to Grozier, be estimated at less than 494,000.

The great mass of the people, however, are employed in productive labour; perhaps, on a rough estimate, full two thirds in agriculture and the fisheries; the remaining third, after deducting the military, the civil officers, the students, and candidates for office, amounting, perhaps, on a rough guess, to about ten millions, are manufacturers, tradesmen, shopkeepers, and the multitudes that are employed in the numerous vessels and barges on the rivers and canals, to carry on the internal commerce of the kingdom. Agriculture is the productive labour that has always received the highest encouragement from the government; and occasionally the emperor himself has turned out into the field with great pomp and solemnity, to hold the plough, as an example to the peasantry. Perhaps, however, as Pauw observes, if they would remove all the trammels from agriculture, it would have a better effect than the continuance of this ancient ceremony. These trammels are, however, fewer and lighter than in most countries. The amount of taxes paid to the state is very small; and the people have neither priesthood nor poor to maintain, each family being compelled by law and custom to take care of its poor relations, and the sovereign taking care of the spiritual concerns of his subjects. The monarch may be considered as the universal and exclusive proprietor of the soil. There is no such thing as freeholds; but undisturbed possession is kept, as long as the holder complies with the conditions on which the land was granted. As there are no public funds, and capital vested in trade is not very secure, nor the profession highly esteemed, the purchase of land is the most eligible mode of rendering capital productive. Still there are very few great landed proprietors. Two reasons may be assigned for this; first, the rate of legal interest being as high as three per cent. for a month, it would be ruinous to borrow money on mortgage; and, secondly, it appears by the penal code, that the proprietorship of the landholder is of a very qualified nature, and subject to a degree of interference and control on the part of government, not known under any of the European governments. It can only be disposed of by will, under certain restrictions; the inheritors must share it under certain proportions. If a proprietor should neglect to register his land in the public records, and to acknowledge himself as responsible for the payment of the taxes, such land would become forfeited. If land capable of cultivation be suffered to lie waste, through the inability of the proprietor to till it, another may obtain permission to cultivate it; and the mortgagee becomes responsible for the payment of the taxes, until the land be redeemed by the proprietor. All these restrictions operate against large landed proprietorships.

Much has been said in praise of Chinese agriculture—much more, in fact, than it deserves. In Europe it would be despised. There are no great farms in China; few families cultivate more than is necessary for their own use, and for payment of the imperial taxes; and without teams of any kind—without any knowledge or practice of a succession of crops—without any grazing farms, for feeding cattle or for the dairy, of which they are totally ignorant—making no use of milk, butter, or cheese—they can have little manure, nor can the land be kept in good condition. In fact, the old fallowing system is followed, and in many parts the spade and the hoe are the great implements of cultivation, their miserable plough scarcely deserving the name. The command of water is the principal substitute for manure. Every substance, however, that can be converted into manure, is most carefully collected; and numbers of old people and children of both sexes find employment in scraping together, with wooden rakes, into their little baskets, whatever may have fallen in the streets or roads, where these

> Lean pensioners upon the traveller's tract
> Pick up their nauseous dole.

Leaves, roots, or stems of plants, mud from the sides of canals, and every sort of offal that presents itself, of which human hair, shaven from the scalps of a hundred millions weekly, forms no inconsiderable ingredient, are carefully scraped together. Large earthen vessels are sunk in the ground, to which, it is said, their cattle are taught to retire; and on the outskirts of many towns and villages are small buildings, invitingly placed for the accommodation of passengers who may have occasion to use them. All these resources, however, are very limited, and the utmost supply thus afforded can only serve for horticultural purposes.

The whole of the land in China under cultivation may be said to be employed exclusively for the subsistence and clothing of man. The staff of life is rice; and it is the chief article of produce in the middle and southern provinces. This grain requires little or no manure; age after age the same piece of ground yields its annual crop, and some of them two crops a year. In the culture of rice, water answers every purpose; and nature has supplied this extensive country most abundantly with that valuable element. It is here that Chinese agricultural skill is most displayed; the contrivances for raising it out of rivers where the banks are high, by means of wheels, long levers, swinging buckets, and the like; or of leading it down from mountain springs, and along terraces levelled on the sides of hills, or in little channels across the plains, are all admirable; but when, from long drought, the rivers run low in their channels, and the springs fail, a scarcity of the crop is the inevitable consequence, and the effects of famine are most dreadful; for though the government has not been wanting in storing up a year's supply of grain in the public magazines (the produce of the taxes being mostly paid in kind), yet, before the beneficent intentions of the sovereign can be carried into effect, there are so many previous memorials and references necessary, and so many forms of office to pass through, that the mischief has worked its effects before the remedy is applied; and though in this vast empire the scarcity of grain may be local and partial, they have no relief to look to from without, and the system of external commerce is too slow in its operations to throw in a timely supply where it may be most wanted. In the northern provinces, where water is less abundant and less to be depended upon, wheat, barley, buck-wheat, and a great variety of millets, supply the place of rice. Everywhere are met with leguminous plants of different kinds, pumpkins, melons, sweet potatoes, and whole fields of a luxuriant vegetable called *pei-tsai*, the white herb, apparently a species of brassica, which is salted for winter consumption. In Kiang-nan and Tche-kiang, vast tracts of land are planted with the white mulberry tree, as food for the silk worms. They appear like a young orchard of cherry trees, being kept low by constant pruning, to make them throw out young shoots and fresh supplies of leaves. In all the middle provinces are large fields of cotton, which article supplies the usual clothing of the great mass of the population; in addition to which, immense quantities are imported annually from Bombay. That peculiar species of a yellowish tinge, which we call Nankin, is not worn by the Chinese, at least in its natural colour; blue, brown, and black, are the prevailing colours. Patches of indigo are generally found in the vicinity of the cotton plantations.

China.

The tea plant, which forms so important an article for the common beverage of the country, and also for exportation, is largely cultivated only in particular provinces, and in certain situations, but is also to be found in gardens and small inclosures in every part of the empire; and has very much of the habit and appearance of the broad-leafed myrtle. It was till recently generally believed that the different kinds of tea were collected from different species of plants. It has now, however, been satisfactorily ascertained that the difference between black and green tea is entirely owing to the mode of preparation. Both sorts undergo the process of *roasting* in their iron pans; the black in a higher degree of heat than the green, which is sufficient to give a different character to the extractive matter from the two sorts; and the nervous quality usually ascribed to green tea may be owing to the little alteration which the juices of the leaf undergo from the small degree of heat that is used in the process. To procure the fine flavour, the Chinese usually press the green teas into the chests and cannisters while hot. They have a practice also of giving a finer bloom to dull-green teas, by sprinkling a little indigo, mixed with powder of gypsum, while stirring the leaf about in the pan. The different sorts of black and green are not merely from soil, situation, and age of the leaf; but, after winnowing the tea, they are taken up in succession as the leaves fall: those nearest the machine, being the heaviest, form the gunpowder tea; the light dust the worst, being chiefly used by the lower classes. That which is brought down to Canton undergoes there a second roasting, winnowing, packing, &c.; and many hundred women are employed for these purposes, the rate of pay being about fifty of their small copper coins, or fourpence per day. The Chinese say that the best tea is that which is gathered in the morning while the dew is on. The gathering in the hyson countries, Kiang-nan and Fokien, commences about the middle of April, and continues till about the middle of May. The collecting, the rolling, the twisting, and roasting, give employment to a multitude of people. From the berry of the *tcha-wha*, or flower of tea (*Camelia sesanqua*), a fine edible oil is extracted. The almond and the *Palma Christi* also afford them an oil for culinary purposes. The white wax is the produce of a tree, or rather of a small insect which frequents the tree; and the *Croton sebiferum* yields an excellent vegetable tallow; both of these articles serving them to make candles. In the southern provinces sugar is a common article of cultivation, but it is rather a luxury than an article of common consumption. It is used mostly in a coarse granulated form; but for exportation, and for the upper classes, it is reduced to its crystallized state. Tobacco is universally cultivated, and in universal use by all ages and both sexes. Fruits of every kind abound, but are mostly bad, except the orange and the *lee-tchee*, both of which are probably indigenous. The art of grafting is well known; but they do not appear to have taken advantage of this knowledge to the improvement of their fruits. They have also an art, which enables them to take off bearing branches of fruit, particularly of the orange and peach, and transfer them, in a growing state, to pots, for their artificial rocks, and grottoes, and summer-houses. It is simply by removing a ring of the bark, plastering round it a ball of earth, and suspending a vessel of water to drop upon it, until it has thrown out roots into the earth. It would require too much space to describe the various vegetable productions used for food and for clothing, for medicine and for the arts. The climate and the soil are well adapted for producing almost all that the rest of the world affords, except, perhaps, those parts which lie within a few degrees of the equator; and the Chinese have obtained their full share even of them.

They are exceedingly sparing in the use of animal food. Those important articles of milk, butter, and cheese, are wholly unknown to them. The broad-tailed sheep are kept in the hilly parts of the country, and brought down to the plains; but the two animals most esteemed, because they contribute most to their own subsistence, and are kept at the cheapest rate, are the hog and the duck. Whole swarms of the latter are bred in large barges, surrounded with projecting stages, covered with coops, for the reception of these birds, which are taught, by the sound of a whistle, to jump into the rivers and canals in search of food, and by another call to return to their lodgings. They are usually hatched by placing their eggs, as the ancient Egyptians were wont to do, in small ovens, or sand-baths, in order that the same female may continue to lay eggs throughout the year, which would not be the case if she had a young brood to attend. The ducks, when killed, are usually split open, salted, and dried in the sun, in which state they afford an excellent relish to rice or other vegetables.

The fisheries are free to all; there are no restrictions on any of the great lakes, the rivers, or canals. The subject is not once mentioned in the *Leu-lee;* but the heavy duties on salt render the use of salt fish in China almost unknown. Besides the net, the line, and the spear, the Chinese have several ingenious methods of catching fish. In the middle parts of the empire, the fishing cormorant, the *Pelicanus piscator*, is almost universally in use; in other parts, they catch them by torch-light; and a very common practice is, to place a board painted white along the edge of the boat, which, reflecting the moon's rays into the water, induces the fish to spring towards it, supposing it to be a moving sheet of water, when they fall into the boat.

When animal food fails them, the Chinese make no scruple in eating lizards, toads, grubs, cats, rats, mice, and many other nauseous creatures. The naked Egyptian dog is commonly exposed for sale in the market. But rice, the hog, and the duck, may be considered as the staple articles of human subsistence for the great mass of the population. Those who can afford it indulge in every species of luxury, and more especially in gelatinous soups, which, while they pamper the appetite, are supposed to excite the passions, and to increase their corpulency, which, in their ideas, confers a degree of respectability and dignity to which a small meagre figure can never arrive

Commerce.

No country in the world is better adapted, from situation, climate, and products, for extensive commerce, than China; yet no civilized country has profited less by these advantages. The happy distribution of its numerous rivers, aided by artificial canals, affords an almost uninterrupted water communication from the northern to the southern, and from the western to the eastern extremities of this grand empire; and in this respect a facility is given for the interchange of the products of one province with those of another, such as is unequalled in any other country in the world. But the commerce that exists is principally that of barter; no system of credit is established between the merchants of distant provinces; no bills of exchange; no circulating medium of any kind, as a common measure of value, excepting a small copper coin, of the value of the thousandth part of 6s. 8d., or about one-third of a farthing. It is impossible to form an idea of the immense number of barges of every variety of form and size that swarm on all the rivers and canals of China. The Chinese themselves are probably not far amiss in stating that the number of imperial barges employed in the Grand Canal and its lateral branches, for the purpose of collecting and distributing among the public granaries the rice and grain paid in kind as taxes, amounts to 10,000, or, as they express it, where they mean to be correct, to 9999. A

China.

vast number of vessels are also employed in conveying the copper currency from place to place, wherever it may be wanted; others in collecting the silks, cottons, and various articles of taxes, paid in kind, and depositing them in the public magazines; and the salt barges alone are probably not less numerous than those which carry grain. It was calculated that the depôt of salt accumulated at Tien-sing for the use of the capital and the northern provinces, was sufficient for a year's consumption for thirty millions of people. This was all brought up, in the course of the summer, from the sea-coast of Tche-kiang and Fokien, in sea-going vessels. Cakes of coal-dust and turf for fuel, and cakes made up of various ingredients for garden manure, employ a multitude of barges; and when to these are added the various kinds of vessels employed in general commerce, in the conveyance of passengers and baggage, in breeding ducks, and in the fisheries of the interior, we may be sure that the number of persons who constantly reside upon the water amounts to many millions. It may be doubted if these are included in any census.

The Chinese government act upon the principle of systematically discouraging all foreign commerce. Satisfied, or affecting to be satisfied, with the prodigal bounty of nature, jealous of strangers, and governed by a gradation of arbitrary despots, the Chinese long considered it as a favour bestowed on foreigners to open any of their ports for the interchange of commodities. The extent, fertility, and variety of their soil and climate, happily situated between the extremes of heat and cold, partaking of the advantages of both, without experiencing the inconveniences of either, have left this great empire, as a nation, almost entirely independent of foreign supplies through the medium of commerce.

The foreign trade at present carried on with China is chiefly in the hands of the English and Americans. The great articles of export are tea and silk, with the former of which China supplies the whole world. The annual consumption of tea in England is estimated at about sixty millions of pounds; in the United States, twenty millions; in Holland, two millions; in Russia, five millions; in Germany, three millions; in Australia, four millions; in France and Spain, three millions. The amount consumed in China itself has been estimated at 700 millions of pounds. The contraband trade in opium is estimated to amount to upwards of 40,000 chests annually.

The Chinese appear to have no regular established system of credit among themselves, and the only circulating medium in the shape of coin is a small piece of base metal (copper, tin, or lead mixed), of the value of the one thousandth part of six shillings and eightpence, of little more intrinsic value, in fact, than a cowrie shell, which the Chinese, as well as the Hindus, would seem once to have used; as the same character in their language which signifies a *shell* signifies also money and wealth, and it enters into the composition of characters which represent *buying*, *selling*, *paying*, &c. Silver in small ingots is used in commerce, but they have no determinate value, the price fluctuating with the demand, as in other articles of commerce. The high rate of interest operates as a discouragement to mercantile speculations, and the rigour of corporal punishment is added with the view, as it would appear, of deterring the most hardy speculator. The law says, "whoever shall lend either money or goods, shall only receive three parts in the hundred per month," and that "how much soever may be suffered to accumulate, the capital shall remain the same." It is lent from month to month, and if the lender should complain of the interest not being punctually paid, the borrower is subject to the punishment of ten stripes of the bamboo the first month, twenty the second, and so on. The legal rate of interest, however, is seldom paid, and in large transactions among business men it is from 12 to 15 per cent. per annum. The borrower makes a special agreement with the lender for a rate of interest varying between these two sums.

General appearance of the country.

When a European first sets his foot in China, he will find the appearance of the country, the buildings, and the people, so totally different from any thing he had before seen, that he might fancy himself to be transported into a new world. In the long line of internal navigation between the capital and Canton, of 1200 miles, with but one short interruption, he will observe every variety of surface, but disposed in a very remarkable manner in great masses. For many days he will see nothing but one uniform extended plain, without the smallest variety; again, for as many days, he will be hemmed in between precipitous mountains of the same naked character, and as unvaried in their appearance as the plains; and, lastly, ten or twelve days sail among lakes, swamps, and morasses, will complete the catalogue of monotonous uniformity. But whether he crosses the dry plains of Petcheli and Shantung, abounding with cotton and all the varieties of grain and pulse,—the more varied surface of Kiang-nan, fertile in silk, in yellow cotton, in fruits, in the staple commodity of grain, and in every thing that constitutes the luxuries, the comforts, and the necessities of the people,—the dreary swamps, morasses, and extensive lakes of the northern part of Kiang-see, where men subsist by fishing,—or its naked and picturesque mountains to the southward, famous for its porcelain manufactories;—or whether he descend to the fertile plains of Quang-tung, on which almost all the vegetable products of the East may be said to be concentrated,—the grand characteristic feature is still the same, namely, a redundant population. Everywhere he meets with large masses of people, but mostly of one sex; thousands of men in a single group, without a single woman mixing among them—men whose long gowns and petticoats give them the appearance of the softer sex; whilst these are sparingly seen at a distance in the background, peeping over the mud-walls, or partially hid behind trees or bushes; and their short jackets and trowsers would make them pass for men among strangers, if their braided hair, stuck full of flowers, and their little cramped and bandaged feet, did not betray their sex. He will be pleased with the unequivocal marks of good humour which prevail in every crowd, uninterrupted and unconcerned by the bawling of some unhappy victim suffering under the lash of magisterial correction; and he will be amused at the awkward exertions of the softer sex to hobble out of sight when taken by surprise; but his slumbers will be interrupted on the nights of the full moon by the nocturnal orgies of squibs and crackers, gongs and trumpets, and other accompaniments of boisterous mirth.

A constant succession of large villages, towns, and cities, with high walls, lofty gates, and more lofty pagodas,—large navigable rivers, communicating by artificial canals, both crowded with barges for passengers and barks for burden, as different from each other, in every river and every canal, as they are all different from any thing of the kind in the rest of the world,—will present to the traveller an animated picture of activity, industry, and commerce. He will behold, in the lakes and morasses, every little islet crowned with villages and mud hovels. He will observe birds (the *leu-tse*, or cormorant) catching fish; and men in the water, with jars on their head, fishing for birds. He will see shoals of ducks issuing from floating habitations, obedient to the sound of a whistle; carts on the land, driven by the wind; and barges on the water, moving by wheels, like those which are now used in Europe for propelling the steam-boats. Among other strange objects, he will observe, at every ten or twelve

miles, small military guard-houses, with a few soldiers fantastically dressed in paper helmets and quilted petticoats, making use of the fan, if the weather be warm, and falling on their knees if an officer of rank should pass them. He will observe that the meanest hut, with walls of clay, and a roof of thatch, is built on the same plan, and of the same shape, with the palace of the viceroy, constructed of blue bricks, and its tiled roof supported on pillars. The use of glass, formerly unknown, is gradually extending throughout the empire, though in the meantime it is only to be found in the houses of the great. Glass windows are superceding the oiled paper, silk gauze, pearl shell, and horn, formerly in use.

Nothing, perhaps, will more forcibly arrest the attention of the traveller than the general nakedness of the country as to trees and hedge-rows, the latter of which have no existence, and the former exist only in clumps near the dwellings of the public officers, or the temples of Fo, or Tao-tse. No green meadows will meet his eye; no cattle enliven the scene; the only herbage is on the narrow ridges which divide the plots of grain or the brown fallow, as in the common fields of England. The terraced hills he will probably observe to be terminated with a clump of trees, or a pagoda, the only objects in the distance that catch the eye. But the bridges on the canals, of every variety of shape, circular, elliptical, horse-shoe, Gothic, slight and unstable as they are, are objects that, by their novelty and variety, must attract notice; and the monumental architecture, which adorns the cemeteries under every form, from the lowly tent-shaped dwelling to the loftiest column—the elevated terraces, supported by semicircular walls—and the round hillocks, which, in their graduated size, point out that of the father, the mother, and the children, according to seniority—are among the most interesting objects that China affords.

If he should happen to enter within the gates of one of their populous cities, as Canton, Pekin, Nankin, Sau-tcheou-foo, or Hong-tcheou-foo, he may fancy himself, from the low houses with curved overhanging roofs, uninterrupted by a single chimney, the pillars, poles, flags, and streamers, to have got into the midst of a large encampment. The glitter arising from the gilding, the varnishing, and the painting, in vivid colours, that adorn the fronts of the shops, and, in particular, the gaily painted lanterns of horn, muslin, silk, and paper; the busy multitude all in motion, and all of one sex; the painted and gilded inscriptions, that, in announcing the articles dealt in, assure the passengers that "they don't cheat here;" the confused noise of tinkers, cobblers, and blacksmiths, in their little portable workshops; the buying, selling, bartering, and bawling, of different wares; the processions of men carrying home their new-married wives, with a long train of presents, and squalling and noisy music, or carrying to the grave some deceased relation, with most lamentable howlings; the mirth and bursts of laughter occasioned by jugglers, conjurors, mountebanks, quack-doctors, musicians, and comedians—in the midst of all which is constantly heard a strange twanging noise from the barbers' tweezers, like the jarring sound of a cracked Jew's harp; the magistrates and officers, attended by their lictors, and a numerous retinue bearing flags, umbrellas, painted lanterns, and other strange insignia of their rank and office;—all these present to the eyes and ears of a stranger a novel and interesting spectacle. The noise and bustle of this busy multitude commence with day-light, and cease only with the setting of the sun; after which scarcely a whisper is heard, and the streets are entirely deserted.

Towards the central parts of China, near to the places where the two great rivers, the Whang-ho and the Yang-tse-kiang, intersect the grand canal, a scene, magnificent beyond description, will arrest the attention of the traveller. Here he will find himself in the midst of bustle and business. The multitudes of ships of war, of commerce, of convenience, and of pleasure, some gliding down the stream towards the sea, others working against it by sails, oars, or wheels, and others lying at anchor; the banks on either side, as well as those of the canals, covered with towns as far as the eye can reach; the continuance along the canals of cities, towns, and villages, almost without interruption; the vast number of light stone bridges, of one, two, and three arches; the temples occurring in frequent succession, with their double and triple tiers of roofs; the Pei-los, or triple gateways, in commemoration of some honest man or chaste virgin; the face of the surrounding country, beautifully diversified with hill and dale, and every part of it in the highest state of cultivation; the apparently happy condition of the numerous inhabitants, indicated by their cheerful looks and substantial clothing, chiefly in silk;—such are the scenes which presented themselves to our countrymen who composed the embassy of the Earl of Macartney, and were afterwards repeated to those who accompanied Lord Amherst.

He would probably be mistaken, however, in inferring the general happy state of the people, or beautiful appearance of the country, from what might occur along this great line of communication between the northern and southern extremities of the empire. The Dutch embassy setting out in winter, when the canals were frozen, proceeded by a different route, and the inconveniences they suffered, as described by Van Braam, are such as can scarcely be credited to have occurred in any nation removed but a few degrees from the savage state. The face of the country was dreary, without a visible trace of cultivation, or a hovel of any kind, for the space of eight or ten miles together. In many parts the surface was covered with water, and the mud hovels completely melted down. Very few cities, towns, or villages, occurred in their route, and those were almost universally in a ruinous condition. Near to the capital they passed a city exhibiting only a mass of ruins. It was not before they had crossed the Yellow River that the prints of wheel carriages marked out the road. The people everywhere appeared indigent and oppressed, equally destitute of the feelings of humanity and hospitality. The Dutch were carried in small bamboo chairs, each having four bearers, so weak and tottering that they could seldom go through the day's journey; and it frequently happened that they halted in the middle of a cold night, in an open uninhabited part of the country, exposed to all the inclemency of the weather, without a hovel of any kind to afford them shelter; and when they reached the end of the day's journey, the lodgings appropriated for their reception were so miserable, admitting on all sides the wind, rain, or snow, that they generally preferred taking a little rest in their bamboo chairs. They observed on the road old men and young women travelling in wheelbarrows, sometimes in litters or chairs carried by a couple of asses, one being fixed between the poles before and one behind. The rivers were without bridges, and crossed, when not fordable, by rafts of bamboo. All this is corroborated in the *Voyage à Peking*, by M. de Guignes; and hence it may be concluded that China, like other countries, has its fertile and its desolate districts, and that much information is yet required to form a competent notion of the real state and condition of this mighty empire. (Staunton's *Authentic Account;* Lord Macartney's *Journal;* Barrow's *Travels; Voyage à Peking;* Van Braam's *Journal; MS. Journal.*)

One thing at least is quite certain, that a traveller in the best and most frequented parts would look in vain for

China. Ornamental gardens.

the least trace of these enchanting gardens, of which Sir William Chambers and his friend Lepqua, the painter of Canton, aided by another brother of the brush, Frère Attiret, Jesuit and painter to the emperor of China, have put together so fanciful a description. Sir William saw, what Europeans generally see in Canton, the shops in China-street, the quay, on which the foreign factories are situated, and perhaps a small mean garden, at the head of the first reach of the river, to which strangers are permitted, as a great favour, to go and buy parcels of lettuce and turnip seeds, neatly packed up, and sold as rare and curious flowers; and the French Jesuit's taste and accuracy may be estimated from his own statement, that "the face of the country from Canton to Pekin is very indifferent; and though six or seven hundred leagues (it is four hundred) nothing occurs worthy of attention." He tells us, it is true, that he was shut up in a kind of close cage, which they laboured to persuade him was a litter, and that he arrived in Pekin without having seen any thing at all on the journey.

With the exception of the imperial gardens of Gehol and Yuen-min-yuen, there is not, perhaps, in all China a piece of ornamental ground of the extent of three acres; and a traveller may pass the whole distance in the open air, which Frère Attiret did in his cage, without seeing a single one of any extent. If he should chance to get a peep within the inclosing walls of those lodges set apart for the residence of the emperor when he travels, or of the habitation of some magistrate or wealthy merchant, he will probably find a square court of a rood or two of ground behind the women's apartments, concealed completely from public view, in which two or three little fish-ponds have their margins fantastically broken by shapeless masses of rock, or cut so as to resemble rugged mountains in miniature; among which, planted in concealed earthen vessels, are dwarfish trees, proportioned in size to the pigmy mountains, and bearing all the marks of venerable age; causing new roots to strike in old branches, twisting and bending them into particular forms and directions, wounding the stem, and smearing it with sugar, to attract the ant and other insects. Among these rocks are narrow paths almost impassable, with holes and crevices here and there to peep through, just to catch a glimpse of some piece of stagnant water, on the shore of which is a wooden temple, a bridge, a pavilion,—or perhaps to view a remarkable piece of rock. Within the water, if large enough, an island with its pagoda will probably be placed; or, as occupying less space, the imitation of a passage-boat stuck upon piles, and fitted up with appropriate apartments, kitchen, &c. In the recesses of the rocks are seats or small summer-houses, opposite to which are parterres of various flowers growing in sunken pots, which can thus be replaced by others in bloom, according to the season of the year; and where there is space, the peach, the orange, the lee-tchee, and other fruit trees, are introduced. From the boundary wall a roof is generally projected, supported on wooden pillars, which forms a covered gallery to walk in; gravel walks are out of the question, and would be wholly inconsistent with the feelings and usage of a nation, the women of which, for whose recreation these gardens are chiefly designed, cannot walk, and whose male population of the upper ranks are too indolent to walk. In short, where secrecy is so desirable, where enjoyments are stolen, and walking is considered as drudgery, seats and concealed recesses are best suited to the comfort and convenience of the people. If a Chinese acts on any principle, it is that of producing the greatest possible variety in the least possible space. He is indebted to nature for many of the most beautiful shrubs and flowers which she has bestowed on man for the gratification of the sense of sight or smell. Various species of camelia, pœonia, chrysanthemum, asters, roses, and a numerous list of the choicest flowers, gratify the eye; while the *Pergularia odoratissima*, the *Olea fragrans*, the *Petrosporum Chinense*, and the Arabian jessamine, spread their fragrance around. The sacred Nelumbium breaks the surface of the water with its peltate leaves and showy flowers, and the elegant bamboo and the water cyprus (*Cupressus pendula*), like the weeping willow, give concealment to their seats of retirement, whether for ease or sensuality.

China. General view of customs and character.

Throughout this extensive empire, embracing so great a variety of climate, the physical and moral characters of the people remain as fixed and unchangeable as the laws and customs, from which, in fact, they receive their colour. Such is the force of ancient usage, and the dread of innovation, that a Chinese never stops to inquire what he ought to do on any pressing emergency, but what Yao and Chun did in a similar case four thousand years ago. Time, in fact, may be said to stand still in China. Here not only the system of morals, of social intercourse, of jurisprudence, of government, is the same now as it was three thousand years ago, but the cut of their robes, their houses and furniture, are precisely the same; so that if custom has exercised its dominion over this singular people, they have at least been freed from the tyranny of fashion. Here a young lady may safely wear the head-dress of her great-grandmother, without the imputation of being singular or old fashioned. One of the missionaries observes, *Parcourez l'empire de la Chine, tout vous semblera fondée dans le même creuset, et façonné par le même moule.* No fault can be found with the metal or the mould in which it is cast. The general stature of the Chinese is about that which in Europe we call the middle size; few tall men are to be found among them, and fewer dwarfs or deformed persons; but they are distinguished by many physical peculiarities, as the narrow, elongated, half-closed eye, the linear and highly arched eye-brow; the broad root of the nose; the projection of the upper jaw a little beyond the lower; the thin straggling beard, and the body generally free from hair; a high conical head and triangular face: and these are the peculiar characteristics which obtained for them, in the *Systema Naturæ* of Linnæus, a place among the varieties of the species distinguished by the name of *homines monstrosi.*

Every individual, without exception, plaits his strong black hair into a long tail, something like the lash of a whip, extending below the waist, sometimes to the calf of the leg. This tail grows from the crown of the head, the rest of the scalp being closely shaven. The hair of the beard is pulled out till nearly the age of forty, when its growth is encouraged, and, being an indication of age, is considered as a mark of respect. The great mass of the people is decently and substantially clothed; the upper and middle classes in rich silks, satins, and fine cottons, the lower orders generally in cottons; but they are not cleanly in their persons, having, apparently, a particular aversion to cold water, which they never use in its pure state as a beverage, and always warm it for washing the hands and face, even in the middle of the dog-days; yet they use ice in the northern provinces for cooling their fruits.

The countenance of a Chinese man has something in it peculiarly pleasing and good humoured, which is just the reverse of that of the women, at least of those in the common rank of life, the only women who are seen in public. A Chinese is never out of humour except when disturbed at his meal; necessity only, not even his own self-interest, will prevail on him to leave his rice unfinished.

The common people seldom sit down to table, or, in fine weather, take their meals within doors; but each with

his bowl in his hand, squatting himself down on his haunches round the boiler, eats his frugal repast of rice or other vegetables, seasoned with a little pork or fish; or salted duck, with oil, fat, or a little soy, washing it down with weak tea, or warm rice beer, or *seau-tcheou*, a villanous ardent spirit. Rice is the staff of life in China, of which they eat largely, but in drinking they are extremely moderate. They are not nice in their choice of food,—dogs, cats, rats, and almost every animal, being eagerly sought after by the poorer class. In such a mass of population, many families must necessarily struggle with all the ills of extreme poverty; fewer, however, it would appear, in proportion to the population, than in most other countries; the small imposts on agricultural produce, the easy terms on which land is procured, the small divisions into which it is partitioned out, the multitude of large rivers, lakes, and canals abounding with fish, the freedom of the fisheries, and the extremely moderate rate at which the agricultural and labouring poor are taxed, are so many spurs to industry; and when a man through age or infirmity becomes incapable of labour, his relations are compelled to contribute to his support; a refusal would be an offence against parental affection, which is not in China a mere moral maxim, but carries with it the force of a positive law; poor-houses are consequently scarcely known, and beggars exist only in the persons of the priests of Fo and Tao-tse and other impostors, in the shape of astrologers and fortune-tellers. Old age is here highly respected, and the imperial family takes every occasion to set the example. On Yung-chin's marriage with a Tartar princess, she distributed a piece of cotton cloth and two measures of rice to every woman throughout the empire whose age exceeded 70 years. In the province of Shang-tung alone, whose population may at that time have amounted to 20,000,000, the list consisted of 98,222 above seventy, 40,893 above eighty, and 3453 above ninety.

In all ranks of life, but more especially among the magistrates and officers of government, vivacity and activity are less esteemed than sedateness and deliberation; gravity is considered as the test of wisdom, and silence of discretion. A magistrate should never attempt to joke, and should forbear to talk; he should resemble great bells, which seldom strike, and full vessels, which give little sound. He should never show his anger, as this would put the person who had offended him on his guard. A Chinese of education is a complete machine; he must act and speak, and walk abroad, dress, receive and return visits, according to rule, founded on ancient usage; the observance of which is a most important part of his duty. If two persons meet, they know from the button on the bonnet their respective ranks; and that alone determines what each has to do and to say. If two officers of equal rank pass each other, they fold their hands and salute each other till out of sight; if of different ranks, the chair or carriage of the inferior must stop, while that of the superior passes; and where the difference is very great, the inferior must alight. It is not, as in Europe, that one person may pass another with indifference, may take off his hat or keep it on, may give or refuse his hand, according to the humour in which he may happen to be; if one of the people should fail to pay the respect that is due to their superiors, a few strokes of the bamboo will bring him back to a sense of his duty. Where there is so much ceremony, there must be much hypocrisy and little cordiality.

When one officer pays a visit to another, a sheet of red paper, folded in a particular manner, bearing the name and quality of the visitor, is dispatched before him, that the person visited may know where to receive him, at the gate, in the first court, or in the inner apartment. The card is accompanied by a list of presents meant to be offered. If part be received, a letter of thanks, and a list of those returned, are sent back, with this observation in two characters, " They are pearls, I dare not touch them;" in allusion to the prohibition of pearls being worn by any except the imperial family, or those who have special leave. The visits of an inferior must always be made before the first meal, that the fumes of meat or wine may not offend the person visited. If he means to decline the visit, the bearer of the card is desired to say to his master, that he will not give him the trouble to alight from his chair; but if he does not return the visit in person, he sends his card within three days, and there the visiting acquaintance ends. Where a visitor is received, a prodigious deal of bowing and ceremony takes place. When once seated, to lounge on the chair, to lean back, to sit cross-legged, or to throw about the arms, or to look round, would be a gross breach of good manners. A cup of tea, sipped simultaneously, according to rule, finishes the formal visit.

These restraints of ceremony, imposed more or less on all conditions of men, are incompatible with frankness and sincerity, and beget that want of confidence between colleagues in office which is particularly observable in this jealous government, by the constant plotting against and undermining each other. The habitual gravity which a magistrate must put on in public stamps an air of importance on matters of the most trifling nature; though it is said they sometimes relax in private, where they indulge in all manner of excesses; and the stiff formality which strongly characterizes this people is said to give way, on such occasions, to conviviality; not, however, unless they are well acquainted with their guests. At such feasts women never appear, but are usually left to be amused by a set of players. To convince the guests how anxious the entertainer is to see them, the invitation is repeated three several times; the first on the preceding evening, the second on the morning of the day, and the third when dinner is ready for serving up, which is the latter of the two meals, and generally from four to six o'clock, according to the season of the year. The guests do not sit down at one table, but generally in pairs, at small square tables, every one of which is served precisely with the same kind of dishes, which are very numerous. Besides the ordinary quadrupeds, birds, and fishes, used as food, several gelatinous articles, as bears' paws, the hoofs of various animals, stags' sinews, sharks' fins, birds' nests, biche-de-mer, fucus or sea-weed, enrich their soups. With these and other substances, mixed with spices, and soys, and various herbs, they have an endless preparation of dishes, served up in small porcelain bowls, eaten with porcelain spoons, and two little ivory or ebony sticks, with which they take the pieces of meat or dry rice, and throw them into the mouth. Pastry and sweetmeats are served up at intervals; tea follows the dinner, after which comes the dessert. Those who, from illness or accident, send an excuse, have their portion of the dinner sent to their homes. Each guest, the next morning, sends a billet of thanks for the good fare he enjoyed the preceding evening.

Though there are tea-houses and cook-shops, to which tradesmen, artizans, and the peasantry, with the inferior officers of state and clerks of the departments, occasionally resort, to refresh themselves and to read the Pekin Gazette, there are no promiscuous assemblies or fixed meetings, as fairs for the lower classes, or routes, balls, or music parties for the higher ranks. Dancing is utterly unknown. The clumsy boots of one sex, and the crippled feet of the other, would be ill adapted for the amusement of dancing, even were the sexes permitted to mix together; but " tripping on the light fantastic toe" would not become that gravity which is so essential in the exterior

of Chinese good breeding. In the former Tartar dynasty, some Lamas from Thibet brought with them to court a set of dancing girls, whose lascivious movements gave great offence to the grave and virtuous Chinese, whose general conduct towards the women is nearly as bad as that which prevails among savage tribes. One may discover in their proverbs the feeling toward the sex. "A family," it is said, "in which there are five women, has nothing to fear from robbers; its poverty will protect it." Again, "When the hen crows in the morning, domestic affairs are not going on as they should be;" and, "What the women have lost in their feet, they have added to their tongues."

It is remarkable enough, that the accurate Marco Polo is wholly silent on the subject of the crippled feet of the Chinese women, which there can be no doubt were as common in his time as they are now. Of the origin of this unnatural custom the Chinese relate twenty different accounts, all equally absurd. Europeans suppose it to have originated in the jealousy of the men, determined, says Pauw, in his severe manner, to keep them "si étroit qu'on ne peut comparer l'exactitude avec laquelle on les gouverne." Whatever may have been the cause, the continuance may more easily be explained: as long as the men will marry none but such as have crippled feet, crippled feet must for ever remain in fashion among Chinese ladies. It is kept up by the pride of superiority and the dread of degradation, like the custom of widows burning themselves in India.

The little value set upon females leads but too frequently to that unnatural crime, female infanticide and exposure. There can be no question as to its existence; the extent of it, however, may have been exaggerated. In the Pekin Gazette of 1815 is a representation from a humane magistrate of Kiang-nan to the tribunal of justice in the capital, praying that the horrible practice of selling and putting away wives and drowning female infants may be prohibited: on which the emperor Kia-king sagaciously observes, that "the existence of male and female is essential to the continuance of the human species;" that "husband and wife form one of the five relationships in which human beings stand to each other;" that "divorce is not allowable except for one of the seven causes;" and concludes, "if it be true that it is a common practice among poor families to drown their female infants, and the husband and wife separate for every trifle, these are indeed wicked practices, which should be put a stop to by admonitory and prohibitory edicts." The magistrates of a district of Fokien sent a case to court on another occasion, to know how they should act. It was this: A man had made a vow that, if his wife recovered from a fit of sickness, he would make a sacrifice of his son, who was three years of age. The wife recovered, and he performed his vow. The supreme court decreed that, having violated the laws of nature, he had incurred the penalty of death; but, on a mistaken notion that, by the unnatural sacrifice, he had saved the life of his mother, the emperor mitigated the punishment to a hundred blows of the bamboo, and perpetual banishment.

This is but a miserable picture of the state of society in China. It is rendered still worse by the common practice of all oriental nations, which admits of a man taking as many wives as he can maintain. In China a second or inferior wife is taken without any ceremony, and generally purchased. The children by her are considered as the children of the first wife, and strictly legitimate; but the mother is without consideration in the eye of law, and may be disposed of in the same way as she was procured.

The athletic exercises of wrestling, boxing, fencing, the active amusements, such as cricket, golf, bowls, tennis, are wholly unknown; and the sports of the field, as hunting, shooting, angling, as pursuits of pleasure, cannot be conceived by them. The Tartars, however, are fond of hunting, of the pleasures of which the Chinese had so little idea, that Kien-lung, in his *Eloge de Moukden*, seems to think it necessary to acquaint them with the benefits arising from this diversion. Having described the pleasures and the dangers of the chase, "Thus," says he, "ends this delightful and highly useful exercise, which is at once propitious to heaven, to the earth, and to the army; to heaven by the offerings it affords in its honour; to the earth, which it relieves from the cruel and pernicious guests that prey upon it; and to the army, by accustoming them to the dangers and fatigues of war."

To appear with the head uncovered, and without boots, would be an act of rudeness not to be tolerated. To receive a present with one hand would be equally rude and disrespectful. To mention the word *death* would be an insufferable rudeness. When a person dies he is said to be gone to his ancestors. Many other peculiarities might be mentioned in which they differ from the rest of the world, and many in which they resemble the Turks in a very marked manner; but this is the less surprising, as the Turks are from the same Scythian stock.

Suicide is no crime with the Chinese. It is a favour to a condemned criminal to allow him to be his own executioner. Women and officers of the government are most addicted to the practice of suicide; the former perhaps from a sense of degradation, or in the gloom of solitude; the latter possibly to escape torture or disgrace when suspected of criminal conduct.

There are two favourable traits in the Chinese character which should not be overlooked,—the respect and veneration of children for their parents, and the almost universal sobriety that prevails in all ranks and conditions of men. A curious story is told by Le Gentil, which he had from Père Laureati, respecting the emperor Kaung-hee, who one day determined to experience the unknown pleasure of getting drunk. He chose his favourite minister as his bottle companion, who contrived to keep sober while his master was unable to stand. The minister apprized the chief eunuch of the emperor's situation, and hinted that, if they did not contrive to cure him of the practice, none of their lives would be safe for a moment. "You must therefore," he continues, "load me with chains, and throw me into a dungeon." Kaung-hee on waking inquired for his companion; the eunuch said that he was in confinement by his orders, for having incurred his displeasure. The emperor doubted his senses; but having ordered the minister to be brought before him, he was so shocked and provoked that he never afterwards ventured to repeat the experiment.

Like other nations, therefore, the Chinese character has its bright as well as its dark side; and if we find the latter to be the most prominent, it should be remembered that it is drawn chiefly by foreigners, and principally by those who have only visited the outports, and whose communication with the interior has been at such rare intervals, that little value is to be attached to their testimony. Here by all accounts they are so much given to knavery and cheating, that it is held to be no crime in the seller to cheat where the buyer is stupid enough to be cheated. Pauw observes that the shopkeepers would never have thought of writing upon their signs, "here nobody will be cheated," if they had not predetermined to cheat all the world; yet our own shopkeepers are not backward in announcing their "genuine" articles. It is to be feared, however, that the boasted morality of the Chinese is built on no principle of feeling or propriety of action between man and man; and that where public decorum is not offended there is no breach of moral duty. Great crimes

China.

are not common, but little vices pervade all ranks of society. A Chinese is cold, cunning, and distrustful; always ready to take advantage of those he has to deal with; extremely covetous and deceitful; quarrelsome, vindictive, but timid and dastardly. A Chinese in office is a strange compound of insolence and meanness. All ranks and conditions have a total disregard for truth; from the emperor downwards the most palpable falsehoods are proclaimed with unblushing effrontery, to answer a political, an interested, or an exculpatory purpose. The emperor asserted, and several great officers of state repeated the assertion to Lord Amherst, that they *saw* Lord Macartney go through the whole of their odious ceremony, and that he performed it to admiration.

These are among the dark shades of the Chinese character; opposed to which may be set his sober and industrious habits, submissive disposition, a mild and affable manner, an exactness and punctuality in all which he undertakes to perform; and if he has not been taught a general philanthropy, or if sentiments of love for the whole species have not been instilled into his mind, he has at least the merit of believing in the God of his fathers, in obeying the commands of his superior, and in honouring his father and mother. Under a better government the Chinese could not fail to become a better people; as it is, some favourable traits may be found, both in the habits of the people and the principles of the government. "Some very considerable and positive moral and political advantages," as Sir George Staunton observes, "are attributable to the system of early and universal marriage; to the sacred regard that is habitually paid to the ties of kindred; to the sobriety, industry, and even intelligence of the lower classes; to the almost total absence of feudal rights and privileges; to the equable distribution of landed property; to the natural incapacity and indisposition of the government and people to an indulgence in ambitious projects and foreign conquests; and, lastly, to a system of penal laws, if not the most just and equitable, at least the most comprehensive, uniform, and suited to the genius of the people for whom it is designed, perhaps of any that ever existed. (J. B—W.)

War with England.

After the discovery of the route to India by the Cape of Good Hope, the Portuguese, Spaniards, Dutch, and English, soon found their way to the coasts of China, and endeavoured to establish commercial relations with that important country. They were allowed for some time to carry on trade at Canton, Amoy, Ningpo, and other places; but, after the accession of the Manchu dynasty, in the middle of the seventeenth century, their privileges were gradually abridged, and at last they were confined to the port of Canton, which alone remained open to European trade. The intercourse of the English with China began considerably later than that of the other maritime nations of Europe. It became, however, far more important in its consequences, and their trade far greater in amount than that of all the other foreign nations together. The first English vessel reached Canton in 1637, and for nearly two centuries the trade was monopolized by the East India Company, and was managed at Canton by a select committee of their supercargoes. In 1833, an act of the British parliament was passed, depriving the company not only of their exclusive right of trading with China, but even of the right of trading with it at all, and authorizing the appointment of superintendents of the trade that should thereafter be carried on by British subjects in China. In terms of that act, the company's monopoly ceased in April 1834, and the select committee announced to the authorities at Canton that their ships would no longer come to China, and that a king's officer would be sent out to superintend the British trade. The only chief, however, that the Chinese expected, was a commercial headman, qualified to communicate with their officers by petition, and through the established medium of the hong-merchants. The new mode of conducting the trade of British vessels was regarded as a trifling matter, affecting only the "outside foreigners." As long as they should be humbly obedient to orders, and duly feel and acknowledge the emperor's kindness, the Chinese cared very little whom they might have for their chief, or what powers he should possess over his countrymen. The first chief commissioner or superintendent appointed by the crown was William John Lord Napier, a captain in the royal navy, who arrived at Macao 15th July 1834, and, in terms of his instructions, announced his arrival by letter to the viceroy. But every effort he made to obtain the recognition of his authority, and to establish a direct official connection with the Chinese rulers at Canton, completely failed; and, worn out with his exertions and disappointment, he died at Macao on the 11th of October following. During 1835 and 1836 matters went on very peaceably under the superintendence of the second and third commissioners, Mr Davis, and Sir G. Robinson; but Mr Davis having returned to England, and Sir G. Robinson having been superseded, Captain Elliot, R.N., became chief commissioner, and renewed the attempt to establish an official connection with the Chinese, but failed as completely as Lord Napier.

The opening of the trade in 1834 gave an immediate stimulus to all kinds of smuggling, and especially in the article of opium, the importation of which into China was prohibited by the imperial government. During the subsequent four years the supply of that drug became immensely increased, and the smuggling trade was extended beyond Canton, along the coasts of the northern provinces. The imperial government becoming seriously alarmed for the possible consequences, not so much for its demoralizing effects as for the continual drain of specie which it occasioned, determined to enforce with the utmost rigour the laws against it. In March 1839 a high imperial commissioner arrived at Canton, and issued an edict requiring that every chest of opium on the river should be delivered up, in order to be destroyed; and that bonds should be given by traders that their ships should never again bring any opium, on pain of forfeiture of the article, and death to the importer. Commissioner Lin having taken strong measures to carry his edict into effect, Captain Elliot proceeded to Canton, and issued a circular letter to his countrymen, requiring them to surrender into his hands all the opium then actually on the coast of China, and holding himself responsible for all consequences. On the 21st of May, the whole of the opium, to the amount of 20,283 chests, was given up to the Chinese government, and immediately destroyed. Even this sacrifice failed to produce the desired effect of leading to peaceful relations with China; for, on the 26th November, Lin issued an edict ordering the cessation of all trade with British ships after the sixth of December; and in January 1840, this was followed by an imperial edict, directing all trade with England to cease for ever.

To put an end to such an unsatisfactory state of things, the British government determined at last to send into the Chinese seas such an armament as should be sufficient to compel the imperial government to acknowledge the principles of international law (which the Chinese had probably never heard of). The first part of the armament reached the Canton river in June 1840, and established a rigorous blockade; but, without attempting further operations there, proceeded northwards, and on 5th July took possession of the large island of Chusan, in the Eastern sea. Captain Elliot proceeded still further north, and, at the mouth of the Peiho river, in the Yellow sea, had a conference with the imperial minister Ke-shen, which resulted in a truce. Ke-shen was appointed imperial commissioner to proceed to Canton for the purpose of investigating the grounds of complaint, and the British plenipotentiaries returned to meet him there.

On 20th January 1841, Captain Elliot issued a circular announcing that a treaty had been agreed to by Ke-shen, stipulating that the island of Hong-kong, situate at the mouth of the bay or gulf of Canton, should be ceded to England, instead of Chusan, which was to be restored to China; that the Chinese government should pay 6,000,000 of dollars as compensation to the English traders; that the trade should be resumed within ten days; and that there should be direct official communication between the two governments on equal terms. On the 26th of that month formal possession was taken of Hong-kong by the British authorities; but on 11th February an imperial edict arrived from Pekin, disapproving of the treaty, rejecting all the terms agreed to by Ke-shen, and degrading and superseding him. Hostilities were immediately resumed: on the 26th February the Bogue forts were taken by the British ships of war, with the loss to the Chinese of 459 guns, and their admiral Kwan, who was killed in the action. After various interruptions and temporary truces, the British forces at last advanced towards Canton; and having got possession of the heights behind the city, which now lay at their mercy, the authorities agreed to pay six millions of dollars for its ransom, and for a cessation of hostilities in that quarter. Five millions having been immediately paid, and security given for the remainder, the British troops were withdrawn, and the trade resumed.

On the 10th of August Sir Henry Pottinger arrived at Macao Roads as the sole commissioner and plenipotentiary of the British government; and on the 12th he sent a communication to the governor of Canton, assuring him that the existing truce would be observed as long as the Chinese should not arm their forts, or impede the regular trade, which had been re-established, or molest the merchants residing in the factories. The trade was carried on at Canton after this without any serious interruption during the remainder of the war.

The expedition proceeded northwards on the 21st; the military forces, numbering about 3500 men, under the command of Major-General Sir Hugh Gough, and the fleet, consisting of two 74-gun ships, seven other ships of war, and a number of transports and other vessels, under the command of Admiral Sir William Parker. Amoy was taken on the 27th, with 500 guns, and large quantities of arms and public stores. Ting-hai, the capital of Chusan, was taken, after a spirited defence, on 1st October, and possession taken again of the whole island. The fleet then proceeded to Chin-hai, which was taken, after a brave defence, on the 10th. On the 13th Ningpo was taken without resistance, and headquarters were established there for the winter. These successes threw the eastern parts of Chekiang open to the invaders, and so alarmed the court of Pekin that on 15th November they issued an edict urging the extermination of the English, and ordering vigorous preparations to be made for the defence of the country. In May 1842, Ningpo was evacuated, and the forces moved up to and took the city of Chapoo. On 13th June the fleet entered the great river Yang-tse. Woosung was taken on the 16th, Shang-hai on the 19th, and on the 18th of July the communication with the great canal was cut off, and all its openings into the river closed. On the 21st the city of Chin-keang was taken, after a gallant defence, and a frightful destruction of life on the part of the inhabitants. On the 9th of August the troops began to disembark at Nankin, and everything was ready for the assault of that city, when, on 12th August, Ke-ying arrived, as imperial commissioner, with full powers to treat of peace. A genuine statement of facts having been sent to the emperor, and the demands of the invaders made known, authority was given to the commissioner to conclude a treaty in accordance with them. On the 29th a treaty of peace was signed before Nankin, on board of the Cornwallis, by Sir Henry Pottinger on the part of Great Britain, and by Ke-ying, Elepoo, and Niu-kien, on the part of the Emperor of China. The most important provisions of the treaty were,—lasting peace and friendship between the two empires; China to pay twenty-one millions of dollars during that and the three succeeding years; the ports of Canton, Amoy, Fuhchau, Ningpo, and Shang-hai, to be thrown open to foreign trade; consular officers to be appointed by foreign powers to reside at these places; regular and just tariffs of import and export and inland transit dues to be established and published; the island of Hong-kong to be ceded in perpetuity to Her Britannic Majesty, her heirs, and successors; and correspondence to be conducted on terms of perfect equality between the officers of both governments. To this important treaty the emperor signified his assent on the 8th of September, and on the 31st of December it was ratified by the British government. In June 1843 the ratifications were exchanged at Hong-kong, which was then taken possession of by proclamation, and the functionaries of government appointed.

The announcement of the treaty of Nankin excited considerable sensation in Europe and America, chiefly in the commercial circles; and agents were sent to China from the governments of Belgium, Holland, Prussia, Spain, and Portugal, and most of them had interviews with Ke-ying at Canton before he returned to court. France and the United States of America sent ambassadors extraordinary to the court of Pekin, but neither of them went farther than Canton. Ke-ying having been re-appointed commissioner for the purpose, a treaty was signed between China and the United States, embodying all the important stipulations of the treaties and commercial regulations agreed to with England, and providing further for the erection of hospitals, chapels, and cemeteries at the five ports, for permission to ships of war to visit any part of the coasts of China; and for the extension of these privileges to all nations. The ratifications of this treaty were exchanged on 31st December 1845. The French ambassador having also arrived at Canton, and entered into negotiation with Ke-ying, a treaty was concluded between them at Whampoa on the basis of that of the United States.

Since then trade has been uninterruptedly carried on at the five ports, but principally at Canton and Shang-hai. The principal articles of export from China are tea and raw silk; and of these the following quantities have been exported during the ten years ending at 1st July 1853:—

		Lb. Tea.	Bales Raw Silk.
Year 1843–4	in 97 vessels	50,613,600

Great rebellion

Under the Ta-tsing or Manchu dynasty, who acquired possession of the empire in 1644, the Chinese appear to have rather declined than advanced in civilization, and the government has long been in a state of great and increasing weakness. The people ceased to respect laws that were openly contemned by public functionaries; piracy and smuggling became acknowledged trades; even robbery was winked at, the mandarins being quieted with a share of the plunder. Ever since the Manchu conquest a large national party has existed, who have been always anxious to restore a native dynasty. These patriots, being closely watched, formed themselves into secret societies. One of these, called the *Pe-lien-kiao*, or Worshippers of the Flower of the White Water-Lily, is said to have been organized like the Society of Jesus, from one of whose members, indeed, the

China.

plan is said to have been obtained. This society soon extended its branches into all the provinces, and its members were supposed to amount to several millions. In 1794 they made a vigorous effort to overthrow the Manchus, and the movement was not entirely suppressed till 1802. Occasional revolts have subsequently occurred; but the society conducted their operations so cautiously that all the efforts of the imperial ministers failed to discover their leaders. Through the influence of these societies, and as the natural consequence of misgovernment among a sober-minded practical people, a general dissatisfaction with their rulers and disgust towards the superstitions of their country were widely diffused, and only required occasion and opportunity for an outbreak.

The sixth emperor of the Ta-tsing dynasty, who had reigned for 29 years under the title of *Taou-kwang*, or the lustre (or brightness or splendour) of reason, died in February 1850, and was succeeded on the throne by his son Yih-choo, who assumed *Hien-fung*, or General Plenty, as the title of his reign. Taou-kwang had latterly become somewhat liberal in his views, and had shown considerable desire to ameliorate the social condition of his people, by favouring the introduction of the useful arts of Europe among them; but, on the accession of Hien-fung, a young, rash, sensual, and narrow-minded prince, his father's ministers were degraded, and mandarins of the old school, inimical to change, came again into power. Reactionary measures were adopted against all innovations, and against all foreign, and especially English influence; but their proceedings served only to awaken in the minds of the people a stern purpose of reform, which immediately showed itself in loud complaints against their rulers. In the following August (1850) a rebellion broke out in the south-western province of Quang-si, where it found a favourable element among the hardy and turbulent mountaineers who dwell on its northern frontier in a state of almost complete independence. Great uncertainty, however, still hangs over the manner of its origin and its immediate cause; and there is no evidence of its having been commenced or conducted at first on any preconcerted or well organized plan. Having overrun a large portion of Quang-si and Quang-tung, and established themselves there, the rebels, for the first time, announced to their fellow countrymen the purposes of their movement, which, they said, were simply to expel or extirpate the Tartars, and to transfer the administration of the public business and revenues into the hands of Chinese officers—not a hint being yet given of the restoration of a prince of the dynasty of Ming to the throne of his ancestors. That was announced for the first time about March 1851, and the name or title of *Tien-teh* (celestial virtue), which the pretender assumed, resounded throughout the empire. During a whole year the measures taken by the imperial government to quell the insurrection had utterly failed; the rebels had made a prosperous beginning, and beaten in detail the armies that had been sent against them; and then came the startling intelligence that the pretender to the empire was in their camp.

The insurrection gathered strength as it proceeded from province to province. Spreading from Quang-si it swept over Hou-quang, and reached the Yang-tse, where the insurgents divided; one body of them proceeding to the attack of the great cities of Han-yang and Wan-choo, while another advanced upon and took Nankin. This was soon followed by the fall of Chin-keang-foo, at the junction of the grand canal with the Yang-tse-kiang; and the possession of that important place rendered the insurgents masters not only of the navigation of the river, but also of the communications between the southern provinces and Pekin. Thence they spread along the sea-coast to the south, and northwards to the Yellow river; and according to the latest intelligence they have advanced to the neighbourhood of Pekin itself. The same spirit seems to actuate them everywhere; they rise only against the hated domination of the Tartars; while relentlessly sacking and destroying every building belonging to the government, and mercilessly slaughtering the Tartars that fall into their hands, they generally respect, and even protect, the persons and property of private individuals not belonging to the proscribed race.

The movement claims for itself the sanction, and even the commission, of Heaven, and has identified itself with the propagation of a new religion. Besides aiming at the overthrow and expulsion of the Tartars, the leaders of the insurrection have announced that they are divinely ordered to exterminate the false priests of Buddha and Taow, to destroy their idols, and to proclaim a loftier creed and a purer code of morals. They have not only announced the revival of the ancient religion of China, in the worship of the true spiritual God, *Shang-ti*, but have connected with it the doctrine of Jesus Christ, as the Saviour of the world. Great mystery has enveloped the real author of this religious scheme, and it was for some time believed that the three names or titles of Hung-sieu-tseuen, Tien-teh, and Tae-ping-wang, by which he was spoken of, represented three individuals. It now appears, however, that these names belong to one person only, the first being his proper name, and the other two, which mean celestial virtue, and the prince of peace, being his assumed titles. This personage is a native of Quang-si, and as it seems of obscure origin; but at the time of his examination for a literary degree at Canton, about 1835, he is said to have got from Leang-afa, a Chinese Christian, a certain tract called "Good words to Admonish the Age," the contents of which seem to have made a strong impression on his mind. Travelling from place to place, he composed books of poetry, and urged his countrymen to receive the new truth. About 1844 he is said to have visited Canton, and to have been for some months an inmate in the house of the missionary Roberts, where he had an opportunity of becoming acquainted with the history and doctrines of the Bible. His writings show that he has had copies of the Pentateuch at least and of the New Testament in his possession, and that he is well acquainted with their contents; but, notwithstanding his knowledge of Christian doctrine, it is said that his writings show very little evidence of these doctrines having taken hold upon his heart; and an eminent Chinese Christian goes the length of saying that there is nothing of Christ in his books. While, however, he manifests such a want of apprehension of the internal and spiritual working of the Christian faith, he exhibits no mean knowledge of the scope and design of Christianity; but that is so intermixed with error and false teaching, and there is said to be such evident tokens of design in his folly, and such a consummate plan in his errors, as to force the conviction on unbiassed minds that the whole of his teaching is a deep-laid plan to acquire power over the minds of his followers, and make them the fitter instruments of his purposes.

The leading object and purpose of his religious teaching seems indeed to be to impress upon the minds of his followers a strong conviction that he is aided and guided by the Almighty and all-knowing God; to inspire them with the certain hope of victory, and to animate their courage by the assurance of endless bliss to all who die in fighting for his cause, and of certain death and eternal destruction to all cowards and traitors. His assurances have been believed, and he has in consequence acquired unbounded control over the huge and heterogeneous masses that have been gathered to his standard. By all accounts they have implicit faith in his divine mission, and have no doubt of his success, and no fear of death. He has likewise announced that he is by divine appointment "monarch of all beneath the sky;" that, as the true lord of China, he is the lord of the whole world; that he is the brother of Jesus, and the

second son of God; and that all the people of the whole world must follow and obey him.

He seems, however, to be something better than a mere political adventurer, or ordinary impostor; he appears to be rather somewhat of a fanatic, a person possessed of a great and dominant idea; and, like some other celebrated persons of the same stamp, it may be that the strength of his own imaginings has led him at last to the sincere belief that he is acting under divine inspirations, which sanctify the use of falsehood and fraud and violence to secure success. It is pretended that an angel was sent by God to carry Sieu-tseuen to heaven, where he was instructed in heavenly things by God himself, furnished by Him with odes and compositions, as also with a seal and sword, and then commissioned, along with Jesus, his elder brother, and with the help of angels, to come down to earth and do battle with the devil and his imps; and that God still continues to favour him with revelations. His book also of celestial decrees contains an account of several appearances of Jesus, to attest the divine commission of Sieu-tseuen; he disclaims, however, certain titles of honour usually given by the Chinese to the emperor, on the ground that they belong only to God. He has published several books or pamphlets containing his doctrines and views, evidently drawn from or founded upon the Bible, and even expressed in scriptural language; and the latest accounts we have of his proceedings inform us of the publication of pure versions of the historical books of both the Old and New Testaments. In these publications he firmly asserts the being of one God, the creator of man, of spirits, and of all things; and hence the determination of his followers to abolish idolatry. He grounds this faith on the Old Testament, as well as on the most ancient books and customs of China. He proclaims the excellence and authority of the ten commandments, and adopts them as his moral law. He has also declared Jesus Christ to be the universal Saviour; has composed forms of prayer for the use of penitent sinners; has declared the existence of an evil spirit, whose power in temptation is to be constantly and perseveringly resisted. Many monstrous and grievous errors are, however, mixed up with these Christian doctrines. It appears that his followers make sacrifices or offerings of slaughtered animals, rice, and fruit, to God; and they still retain the national custom of polygamy, and reckless disregard for the sanctity of human life.

This great movement has been ascribed by some to the operations of the secret societies; while others trace it to the influence of the Christian missionaries that have been labouring for centuries among the Chinese. Christianity is no new thing in China. In the seventh and following centuries it was introduced and widely diffused by Nestorian missionaries, who are even said to have prepared that translation of the Scriptures into the Chinese language which has been made use of by Sieu-tseuen. Before the fifteenth century the Christianity so introduced had almost completely died out. In the sixteenth the Jesuits commenced their missionary labours in China; and the Romanists have been ever since perseveringly endeavouring to convert the natives; but hitherto, it appears, with very indifferent success, even though they have numbered their proselytes by hundreds of thousands.

They have introduced rites and ceremonies, and new objects of worship, in abundance; they have even martyrs and confessors to boast of, but they have never introduced a version of the Scriptures. Latterly, Protestant missionaries have been engaged in the work of Christianizing China; but neither of these rival parties seems entitled to claim the honour of originating the great movement that is now in progress. There is an absence of everything that would indicate Roman influence, and the Romanists themselves avow that they find no Catholic element in it. The adoption also of the word *Shang-ti* as the name of God, in opposition to *Tien-chu*, the word that was sanctioned by Pope Clement XI. in 1715, and the title of "worshippers of Jesus" given to the insurgents, are virtually a protest against Romanism, which has acquired, in popular language, the name of *Tien-chu-kiao*, or "the worship of the Lord of heaven." The whole spirit of the movement is alien to the genius of the Romish Church, and is characterized rather by reckless impetuosity than by tame subserviency, or the blind subjection of thought and action to the dictates of their leaders. The movement, however, neither seems to indicate very intimate connection with the doctrines preached by the Protestant missionaries, nor to be owing in any degree to their personal influence or exertions, as the published books of the insurgents are said to be absolutely free from any trace of the party spirit or symbolism and conventional language of any of the rival sectaries of Protestant Christendom.

CHINA-Ink, a pigment made of lamp-black and gelatine, or isinglass, well incorporated by levigation on a stone slab. It is usually perfumed slightly with musk or with camphor. The finest kind is said to be prepared in the East from the soot obtained by burning camphor. When prepared in the ordinary way, the addition of a minute quantity of alkali is an improvement, as it serves to saponify any oily matter, and thereby renders the pigment more readily miscible in water.

CHINA-Root, the root of a species of Smilax, once used in medicine, but now discarded from our pharmacopœias, being superseded by sarsaparilla. It comes from the West Indies as well as from China; but that from the latter is much superior to the other.

China-*Ware*. See Porcelain.

CHINCHILLA, a city of Spain, province of Murcia, picturesquely situated on an abrupt hill ten miles S.E. of Albacete. Pop. 7565. It is surrounded by old walls, defended by a citadel, and has manufactures of earthenware and coarse linen and woollen cloths.

Chinchilla, a small animal of the order *Rodentia*, from which a valuable fur is obtained. See index to Mammalia.

CHINGLEPUT, the chief town and fortress of a district of the same name, on the N.E. bank of the Palar river, 36 miles S.S.W. from Madras. In 1751 Chingleput was taken by the French, and retaken in 1752 by Clive. During the wars of the British with Hyder Ali, it was one of the few strongholds which withstood his power, and afforded a secure refuge to the natives. In 1780, after the defeat of Colonel Baillie, the army of Sir Hector Munro sought protection under its walls. It is now the residence of the British civil establishment, namely, the judge, collector, &c. The town is noted for its manufacture of pottery. Long. 80. 2.; Lat. 12. 41.

The district of Chingleput is bounded N. by Nellore; E. by the bay of Bengal; S. by South Arcot; and W. by North Arcot. Within its limits is situated the city of Madras. Area about 3000 square miles. Pop. 583,462. It was obtained from the nabob of Arcot in 1763; and the cession was confirmed by the emperor of Delhi in 1765.

CHIN-HAE, a district town of China, province of Chekiang, at the mouth of the Yung-kiang river, 12 miles N.E. of Ningpo, N. Lat. 25. 58., E. Long. 121. 35. It lies at the foot of a hill on a tongue of land, and is partly protected from the sea on the N. by a dike about 3 miles long, composed entirely of large blocks of hewn granite. The walls are 20 feet high and 3 miles in circumference, but suburbs extend along the shore for the convenience of the shipping. The defences consist of two batteries on the river side, and a well built citadel on a precipitous cliff, 250 feet high at the extremity of the tongue of land on which the town

is built. In the neighbourhood an engagement took place between the English and Chinese in October 1841.

CHIN-KIANG-FU, a maritime city of China, province of Kiang-su, at the junction of the Grand Canal with the Yang-tse-kiang, 48 miles E.N.E. of Nankin. This city was taken by the British after a desperate resistance on 21st July 1842.

CHINON, a town of France, capital of a cognominal arrondissement, department of Indre-et-Loire, pleasantly situated on the right bank of the Vienne, 28 miles S.W. of Tours. Pop. (1851) 6675. It has a tribunal of primary instance, a communal college, and some trade in grain, dried fruits, wine, brandy, &c. Here Henry II. of England died in 1189; and the ruins of the castle where Charles VII. of France resided after the occupation of Paris by the English, and where Joan of Arc presented herself to him, are still seen. Rabelais was born at a hamlet in the vicinity in 1483.

CHINSURA, a town situated in the western bank of the Bhagarutty or Hooghly river, 24 miles above Calcutta, and formerly the principal Dutch settlement in Bengal. It was among the cessions on the continent of India made by the king of the Netherlands in 1824 in exchange for the British possessions in the island of Sumatra. The Dutch erected a factory here in 1656, on a clear and healthy spot of ground, much preferable to that on which Calcutta is situated, and soon attracted a considerable number of natives to settle in the vicinity. About thirty-five years after this they fell under the displeasure of one of the native potentates, who sequestrated their property and prohibited their traffic. In 1686 all their factories were re-established, and their trade long continued to flourish. In 1759 a British force under Colonel Forde was attacked by the garrison of Chinsura on its march to Chandernagore. The action was short but decisive; for in less than half an hour the Dutch were entirely routed. In 1795, when Holland became a province of France, the British offered to retain Chinsura for the stadtholder; but the governor having declined to surrender, the settlement was reduced by a detachment from the military stations at Barrackpore, and was occupied by a British garrison during the whole war. At the general peace of 1814 it was restored to the Dutch. The town, which extends for half a mile along the banks of the river, is built neatly, and with great solidity, of brick and mortar. The houses are plastered with fine lime, and have flat roofs and green Venetian windows. Long. 88. 23. E., Lat. 22. 52. N.

CHIO, or CHIOS. See SCIO.

CHIOGGIA, a seaport-town of Northern Italy, government of Venice, and 15 miles S. of that city, situated on a cognominal island at the southern extremity of the lagoon of Venice. It consists of a long wide street extending the whole length of the island, with smaller streets branching off at right angles; and is connected with the mainland by a low stone bridge of 43 arches. It is the seat of a bishop, and has a theological seminary, several schools and charitable institutions, shipbuilding yards, and important salt-works. Pop. 25,000, principally engaged in the coasting trade, in fishing, and in piloting vessels into the harbour of Venice.

CHIONE, in *Grecian Mythology*, daughter of Dædalion, was beloved by Apollo and Mercury, by whom she became the mother of twins, Philammon and Autolycus. The first, being the son of Apollo, excelled as a musician; while Autolycus became no less famous for those robberies of which his father Mercury was supposed to be the patron. Chione was killed by Diana because she had the arrogance to compare her beauty with that of the goddess. Chione is also called Philonis. (Ov. *Met.* xi. 300; Hygin. Fab. 200.) There was also another Chione, daughter of Boreas and Orithyia. By Neptune she became the mother of Eumolpus, whom she threw into the sea; but Neptune saved the child.

CHIPPENHAM, a parliamentary and municipal borough and market-town of England, hundred of the same name, in Wiltshire, 30 miles N.N.W. of Salisbury, and 94 miles from London by the Great Western railway. It stands in a valley on the left bank of the Avon, which is here crossed by a handsome stone bridge of 22 arches. Chippenham is governed by a mayor, 4 aldermen, and 12 councillors, and returns 2 members to parliament. Pop. (1851) of parliamentary borough, 6283; of municipal borough, 1707. The town consists chiefly of one well-built street more than half a mile in length, and has a spacious Gothic church, town-hall, market-house, savings-bank, literary institution, free school, a silk factory, corn-mills, tanneries, and manufactures of woollens. Market-day Friday.

CHIPPEWAY INDIANS. See AMERICA, vol. ii., p. 680.

CHIPPING, CHIP, CHEAP, in the names of places, signify a market; from the Saxon *ceapan* or *cypan*, to buy or sell. Hence Chipping-Norton, Chippenham, Cheapside. The word *chapman* also is from the same root.

CHIPPING-NORTON, a municipal borough and market-town of England, hundred of Chadlington, county and 18 miles N.W. of Oxford. It is governed by a mayor, 4 aldermen, and 12 councillors; and returned 2 members to parliament in the 30th of Edward I., and the 32d and 33d of Edward III. It has a town-hall, 2 churches, 3 chapels, a free grammar-school, almshouses, and several charities. The parish church is a fine large Gothic edifice. Market-day Wednesday. Pop. (1851) 2932.

CHIPPING-SODBURY, a market-town, hundred of Grumbald's Ash, Gloucestershire, 27 miles S.S.W. from Gloucester, and near the Yate station of the Bristol and Gloucester railway. It contains one parish and various dissenting churches, with several schools and charitable institutions. The population is chiefly agricultural, the principal articles of trade being malt and cheese, for the sale of which there are monthly markets, and two annual fairs. Near the town are several quarries and coal-pits; and about two miles from it there are Roman remains. Pop. of parish (1851) 1195.

CHIQUITOS, a province of Bolivia, department of Santa Cruz. It is thinly inhabited, on account of the swamps which occupy a large portion of the interior, and render it both sterile and unhealthy. See BOLIVIA.

CHIROGRAPH (χείρ the hand, γράφω to write), an ancient kind of deed which, requiring a counterpart, was engrossed twice on the same piece of parchment counterwise, with a space between in which was written CHIROGRAPH, through which the parchment was cut, and one part given to each party. It answered to what is now called a *charter-party*. Chirographs were first used in England in the time of Henry III.

CHIROMANCY, a species of divination drawn from the lines of the hand, by which fortune-tellers pretend that the dispositions, &c., may be discovered.

CHIRON, a famous personage of antiquity, styled by Plutarch, in his dialogue on music, *the wise Centaur*. Sir Isaac Newton places his birth in the first age after Deucalion's deluge, commonly called the Golden Age; and adds, that he formed a scheme of the constellations for the use of the Argonauts when he was eighty-eight years of age, fixing with accuracy the solstitial and equinoctial points.[1] Chiron may, therefore, be said to have flourished in the earliest ages of Greece, as he preceded the Argonautic

[1] Sir Isaac Newton has founded his emendation of the ancient chronology on a calculation of the regular precession of the equinoxes from this period to the present, as well as on an estimate of the medium length of human generations. Tytler's *Elements of History*.

expedition and the Trojan war. He is generally called the son of Saturn and Philyra; and he is said to have been born in Thessaly among the Centaurs, the first Greeks who acquired the art of breaking and riding horses; from which circumstance the poets, painters, and sculptors have represented them as a compound of man and horse; and perhaps it was imagined by the Greeks, as well as the aboriginal Americans when they first saw cavalry, that the horse and the rider constituted but one animal.

Chiron was represented by the ancients as one of the first inventors of medicine, botany, and chirurgery; which last word some etymologists have derived from his name.* He inhabited a grotto or cave at the foot of Mount Pelion, which, from his wisdom and great knowledge of all kinds, became the most celebrated and frequented school throughout Greece. Almost all the heroes of his time were fond of receiving his instructions; and Xenophon, who enumerates them, names the following illustrious personages among his disciples: Cephalus, Æsculapius, Melanion, Nestor, Amphiaraus, Peleus, Telamon, Meleager, Theseus, Hippolytus, Palamedes, Ulysses, Mnestheus, Diomedes, Castor and Pollux, Machaon and Podalirius, Antilochus, Achilles, and Æneas. From this catalogue it appears that Chiron frequently instructed both fathers and sons; and Xenophon has recorded a short eulogium on each, which may be read in his works. The Greek historian, however, has omitted naming several of his scholars, such as Bacchus, Phœnix, Cocytus, Arystæus, Jason and his son Medeus, Ajax, and Protesilaus. It is pretended that the Grecian Bacchus was the favourite scholar of the Centaur; and that he taught this master the revels, orgies, bacchanalia, and other ceremonies of his worship. According to Plutarch, it was likewise at the school of Chiron that Hercules studied music, medicine, and justice; although Diodorus Siculus affirms that Linus was his instructor in this art. But of all the heroes who were desciples of the Centaur, none reflected so much honour upon him as Achilles, whose renown he in some measure shared, and to whose education he in a particular manner attended, being his grandfather by the mother's side. Apollodorus tells us, that music occupied a considerable part of the time which he devoted to the instruction of his young pupil, and that he viewed it as an incitement to virtuous actions, and a bridle to the impetuosity of his temper. One of the best remains of antique painting now extant is a picture on this subject, dug out of the ruins of Herculaneum, in which Chiron is represented in the act of teaching the young Achilles to play on the lyre. The death of this philosophical musician was occasioned, at an extreme old age, by an accidental wound in the knee with a poisoned arrow, aimed by his scholar Hercules at another person. After his death he was placed by Musæus among the constellations, from respect for his virtues, and in gratitude for the great services which he had rendered the people of Greece. Sir Isaac Newton says, in proof of the constellations being formed by Chiron and Musæus for the use and honour of the Argonauts, that nothing later than the expedition was delineated on the sphere; and according to the same author, Chiron lived till after the Argonautic expedition, in which he had two grandsons. The ancients have not failed to attribute to him several writings, among which, according to Suidas, are *precepts*, ὑποθῆκαι, in verse, composed for the use of Achilles; and a medicinal treatise on the diseases incident to horses and other quadrupeds; and the lexicographer even pretends that it is from this work that the Centaur derived his name. Fabricius gives a list of the works attributed to Chiron, and discusses the claims which have been set up for others to the same writings; at the same time giving him a distinguished place in his catalogue of ancient physicians.

CHIRONOMY, the science which treats of the rules of gesticulation, which is one part of pantomime. Among the ancients this formed part of a liberal education; and it received the approbation both of Socrates and Plato.

CHISEL (French *ciseau*), an instrument used in sculpture, masonry, joinery, carpentry, &c., for paring, hewing, or gouging.

CHISLEV, the name of the third month of the civil, and the ninth of the ecclesiastical year of the Jews, commencing with the new moon of our December.

CHISWICK, a village on the north bank of the Thames, Middlesex, 4½ miles from Hyde Park Corner, contains numerous fine villas, the principal of which is Chiswick House, the residence of the Duke of Devonshire. The parish church is ancient, and in the churchyard is the tomb of Hogarth. In the neighbourhood are the gardens of the Horticultural Society, and extensive market-gardens for the supply of the metropolis. Chiswick is a station of the loop line of the South-Western railway. Pop. of parish (1851) 6303.

CHITORE, or CHETORE, in Hindustan, a town with a fortress, and formerly the capital of the Rajpoot state of Odeypoor. It is situated on the top of a high and rugged mountain, and is considered a place of great strength. In 1303 it was taken by the Mohammedan emperor of Delhi, by whom, however, it was subsequently granted to the nephew of its former ruler, subject to the payment of tribute, and on condition of furnishing an armed feudal force of 5000 horse, and 10,000 foot. In 1533 it surrendered to Bahadur Shah, king of Guzerat, from whom it was shortly after wrested by Humayon, emperor of Delhi, who reinstated the Rajpoot prince. In 1567 it was taken by the armies of the emperor Acbar. The place was garrisoned by 8000 disciplined Rajpoots, who made an obstinate defence; and when driven to despair, sacrificed their women and children, and were trampled to death by the war elephants introduced into the place by the emperor. The fort appears to have been subsequently recovered by the chief of Odeypoor, and to have been recaptured by the Moguls in 1680 during the reign of Aurungzebe, when 63 Hindu temples were destroyed. On the dismemberment of the empire of Delhi, Chitore reverted to the Rajpoots. For a short period it was held by a rebel named Bheem Singh; but the insurgent chief being dispossessed by Scindia, the fortress in 1790 was restored to its lawful possessor the Rana of Odeypoor, under whose dominion it still remains. Distant from Neemuch N.W. 30 miles; from Agra S.W. 270. Lat. 24. 52., Long. 74. 41.

CHITTAGONG, a British district under the presidency of Bengal, bounded on the N. by the Hill state of Tipperah, on the E. by the Youmadoung mountains separating it from Burmah, on the S. by Arracan, and on the W. by the bay of Bengal. Its area, irrespective of the mountainous tract inhabited only by wild tribes, has been returned at 2717 square miles, supporting a population estimated at a million. Aurungzebe, emperor of Delhi, wrested this province from the rajah of Arracan towards the close of the seventeenth century, and annexed it to the imperial dominions. It formed one of the earlier acquisitions of the East India Company, having been ceded to them by the nawaub of Bengal in 1760. Its cession was insolently demanded by the king of Ava in 1824, previous to the breaking out of the first Burmese war, under the pretext that previous to its conquest by Aurungzebe it formed a dependency of Arracan, then a portion of the Burmese dominions. The district extends from Lat. 20. 45. to 23. 25.; and from Long. 91. 32. to 93.

CHITTLEDROOG, a town and celebrated fortress of Hindustan, and capital of a district belonging to the rajah of Mysore. The fort is situated on a rock which is surrounded by walls, and is considered as impregnable. Around it are low, rocky, bare hills. It was besieged without effect by Hyder Ali in 1776; but three years later the fortress

fell into the possession of that prince, who had bribed the Mohammedan part of the garrison. The fort was used by Tippoo Sultan as a state prison, in which, among many other captives, native and British, General Matthews was incarcerated in 1783 after the capitulation of Bednore. Distant from Seringapatam N. 128 miles. Lat. 14. 14.; Long. 76. 27.

CHITTOR, a town and fortress of Hindustan, situated among mountains, on the western frontier of the Carnatic, 80 miles W. from Madras. It was in 1721 the residence of the military commander of the district, Tahir Khan, and was well fortified. It was selected by the nawaub Anwarradden Khan as a place of refuge in times of danger. It was occupied by his younger son, with several females of the family, when it was assaulted and taken in 1780 by Hyder Ali. It was afterwards retaken by Sir Eyre Coote. In 1801 it was made over to the British; and the polygars, who were extremely turbulent and refractory, were reduced by a military force sent against them in 1804. Long. 79. 10. E.; Lat. 13. 12. N.

CHIUSA, or LA CHIUSA, a town on the Pesio, province of Coni, kingdom of Sardinia. It has a population of about 5600, chiefly engaged in the manufacture of silk and glass.

CHIVALRY.

THE primitive sense of this well-known word, derived from the French *chevalier*, signifies merely cavalry, or a body of soldiers serving on horseback, and has been used in that general acceptation by the best of our poets, ancient and modern, from Milton to Thomas Campbell.

But the present article respects the peculiar meaning given to the word in modern Europe, as applied to the order of knighthood, established in almost all her kingdoms during the middle ages, and the laws, rules, and customs, by which it was governed. These laws and customs have long been antiquated, but their effects may still be traced in European manners; and, excepting only the change which flowed from the introduction of the Christian religion, we know no cause which has produced such general and permanent difference betwixt the ancients and moderns as that which has arisen out of the institution of chivalry. In attempting to treat this curious and important subject, rather as philosophers than as antiquaries, we cannot, however, avoid going at some length into the history and origin of the institution.

Origin of the institution.

From the time that cavalry became used in war, the horseman who furnished and supported a charger rose, in all countries, into a person of superior importance to the mere foot soldier. The apparent difficulty of the art of training and managing in the field of battle an animal so spirited and active, gave the ἱππόδαμος, or *domitor equi*, in rude ages, a character of superior gallantry, while the necessary expense attending this mode of service attested his superior wealth. In various military nations, therefore, we find that horsemen were distinguished as an order in the state; and we need only appeal to the *equites* of ancient Rome as a body interposed betwixt the senate and the people; or to the laws of the conquerors of New Spain, which assigned a double portion of spoil to the soldier who fought on horseback, in support of a proposition in itself very obvious. But in the middle ages the distinction ascribed to soldiers serving on horseback assumed a very peculiar and imposing character. They were not merely respected on account of their wealth or military skill, but were bound together by an union of a very peculiar character, which monarchs were ambitious to share with the poorest of their subjects, and governed by laws directed to enhance into enthusiasm the military spirit, and the sense of personal honour associated with it. The aspirants to this dignity were not permitted to assume the sacred character of knighthood until after a long and severe probation, during which they practised, as acolytes, the virtues necessary to the order of chivalry. Knighthood was the goal to which the ambition of every noble youth turned; and to support its honours, which, in theory at least, could only be conferred on the gallant, the modest, and the virtuous, it was necessary he should spend a certain time in a subordinate situation, attendant upon some knight of eminence, observing the conduct of his master, as what in future must be the model of his own, and practising the virtues of humility, modesty, and temperance, until called upon to display those of a higher order.

The general practice of assigning some precise period when youths should be admitted into the society of the manhood of their tribe, and considered as entitled to use the privileges of that more mature class, is common to many primitive nations. The custom also of marking the transition from the one state to the other by some peculiar formality and personal ceremonial, seems so very natural, that it is quite unnecessary to multiply instances, or crowd our pages with the barbarous names of the nations by whom it has been adopted. In the general and abstract definition of chivalry, whether as comprising a body of men whose military service was on horseback, and who were invested with peculiar honours and privileges, or with reference to the mode and period in which these distinctions and privileges were conferred, there is nothing either original or exclusively proper to our Gothic ancestors. It was in the singular tenets of chivalry,—in the exalted, enthusiastic, and almost sanctimonious ideas connected with its duties,—in the singular balance which its institutions offered against the evils of the rude ages in which it arose,—that we are to seek those peculiarities which render it so worthy of attention.

The original institution of chivalry has often been traced to the custom of the German tribes recorded by Tacitus. "All business," says the historian, "whether public or private, is transacted by the citizens under arms; but it is not the custom that any one shall assume the military dress or weapons without the approbation of the state. For this purpose, one of the chief leaders, or the father or nearest relation of the youthful candidate, introduces him into the assembly, and confers on him publicly a buckler and javelin. These arms form the dress proper to manhood, and are the first honour conferred on youth. Before he receives them the young man is but a member of his own family, but after this ceremony he becomes a part of the state itself." (Taciti *Germania*.) The records of the northern nations, though we cannot rely upon their authenticity with the same unlimited confidence, because we conceive most of the legends relating to them have been written at a much later period than the times in which the scene is laid, may be referred to in confirmation of the Roman historians. The Scandinavian legends and *Sagas* are full of the deeds of those warriors whom they termed heroes or champions, and who appear to have been formed into an order somewhat resembling that of chivalry, and certainly followed the principal and most characteristic employment of its profession,—wandering from court to court and from shore to shore, bound on

high adventure, and seeking with equal readiness their fortunes in love and in war. It would not be difficult to deduce from this very early period some of those peculiar habits and customs, which, brought by the Gothic conquerors into the provinces of the divided empire of Rome, subsisted and became ingrafted upon the institutions of chivalry. Tacitus, for example, informs us, that among the Germans, and especially among the Catti, every youthful champion permitted his beard and hair to grow, and did not shave them until he had performed some signal feat of arms. In the like manner, as the general reader may have learned from that irrefragable authority, Don Quixote de la Mancha, a knight who received his order was obliged to wear white armour, and a shield without a device, until, by some daring and distinguished achievement, he had acquired title to an honourable badge of distinction. If this correspondence of customs shall be thought too far fetched and too general, the next, which we also derive from Tacitus, is too close to be disputed. The German warriors who piqued themselves upon this bravery, used, at the commencement of a war, to assume an iron ring, after the fashion of a shackle, upon their arm, which they did not remove until they had slain an enemy. The reader may be pleased to peruse the following instance of a similar custom from the French romance of *Jehan de Saintré*, written in the year 1459, and supposed to be founded, in a great measure, upon real incidents.[1] The hero, with nine companions at arms, four of whom were knights, and five squires, vowed to carry a helmet of a particular shape, that of the knights having a visor of gold, and that of the squires a visor of silver. Thus armed, they were to travel from court to court for the space of three years, defying the like number of knights and squires, wherever they came, to support the beauty of their mistresses with sword and lance. The emblems of their enterprise were chained to their left shoulders, nor could they be delivered of them until their vow was honourably accomplished. Their release took place at the court of the emperor of Germany, after a solemn tournament, and was celebrated with much triumph. In like manner, in the same romance, a Polish knight, called the Seigneur de Loiselench, is described as appearing at the court of Paris wearing a light gold chain attached to his wrist and ankle in token of a vow; which emblem of bondage he had sworn to wear for five years, until he should find some knight or squire without reproach, by encountering with whom he might be *delivered* (such was the phrase) of his vow and enterprise. Lord Herbert of Cherbury mentions, in his memoirs, that when he was made knight of the bath, a tassel of silken cordage was attached to the mantle of the order, which doubtless had originally the same signification as the shackle worn by the German champion. The rule was, however, so far relaxed, that the knot was unloosed so soon as a lady of rank gaged her word that the new knight of the bath would do honour to the order; and Lord Herbert, whose punctilious temper set great store by the niceties of chivalrous ceremony, fails not to record, with becoming gratitude, the name of the honourable dame who became his security on this important occasion.

Other instances might be pointed out, in which the ancient customs of the Gothic tribes may be traced in the history of chivalry; but the above are enough to prove that the seeds of that singular institution existed in the German forests, though they did not come to maturity until the destruction of the Roman empire, and the establishment of the modern states of Europe upon its ruins.

Having thus given a general view of the origin of chivalry, we will, I. Briefly notice the causes from which it drew its peculiar characters, and the circumstances in which it differs so widely from the martial character as it existed, either among the ancient Greeks and Romans, or in other countries and nations. II. We will attempt a general abstract of its institutions. III. The rise and progress of chivalry, its effects upon the political state of Europe, and its decay and extinction, will close the article.

I. Agreeably to this general division, the general nature and spirit of the institution of chivalry falls first under our consideration.

Peculiar nature and spirit of this institution.

In every age and country valour is held in esteem, and the more rude the period and the place, the greater respect is paid to boldness of enterprise and success in battle; but it was peculiar to the institution of chivalry to blend military valour with the strongest passions which actuate the human mind—the feelings of devotion and those of love. The Greeks and Romans fought for liberty or for conquest, and the knights of the middle ages for God and for their ladies. Loyalty to their sovereigns was a duty also incumbent upon these warriors; but although a powerful motive, and by which they often appear to have been strongly actuated, it entered less warmly into the composition of the chivalrous principle than the two preceding causes. Of patriotism, considered as a distinct predilection to the interests of one kingdom, we find comparatively few traces in the institutions of knighthood But the love of personal freedom, and the obligation to maintain and defend it in the persons of others as in their own, was a duty particularly incumbent on those who attained the honour of chivalry. Generosity, gallantry, and an unblemished reputation, were no less necessary ingredients in the character of a perfect knight. He was not called upon simply to practise these virtues when opportunity offered, but to be sedulous and unwearied in searching for the means of exercising them, and to push them without hesitation to the brink of extravagance, or even beyond it. Founded on principles so pure, the order of chivalry could not, in the abstract at least, but occasion a pleasing, though a romantic development of the energies of human nature; but as, in actual practice, every institution becomes deteriorated and degraded, we have too much occasion to remark, that the devotion of the knights often degenerated into superstition,—their love into licentiousness,—their spirit of loyalty or of freedom into tyranny and turmoil,—their generosity and gallantry into hairbrained madness and absurdity.

We have mentioned devotion as a principal feature in the character of chivalry. At what remote period the forms of chivalry were first blended with those of the Christian religion, would be a long and difficult inquiry. The religion which breathes nothing but love to our neighbour and forgiveness of injuries, was not, in its primitive purity, easily transferable into the warlike and military institutions of the Goths, the Franks, and the Saxons. At its first infusion, it appeared to soften the character of the people among whom it was introduced so much, as to ren-

[1] We may here observe, once for all, that we have no hesitation in quoting the romances of chivalry as good evidence of the laws and customs of knighthood. The authors, like the painters of the period, invented nothing, but, copying the manners of the age in which they lived, transferred them without doubt or scruple to the period and personages of whom they treated. But the romance of *Jehan de Saintré* is still more authentic evidence, as it is supposed to contain no small measure of fact, though disguised and distorted. Probably the achievement of the Polish knights may have been a real incident.

der them less warlike than their heathen neighbours. Thus the pagan Danes ravaged England when inhabited by the Christian Saxons,—the heathen Normans conquered Neustria from the Franks,—the converted Goths were subdued by the sword of the heathen Huns,—the Visigoths of Spain fell before the Saracens. But the tide soon turned. As the necessity of military talent and courage became evident, the Christian religion was used by its ministers (justly and wisely, so far as respected self-defence) as an additional spur to the temper of the valiant. Those books of the Old Testament which Ulphilas declined to translate, because they afforded too much fuel for the military zeal of the ancient Goths, were now commented upon to animate the sinking courage of their descendants. Victory and glory on earth, and a happy immortality after death, were promised to those champions who should distinguish themselves in battle against the infidels. And who shall blame the preachers who held such language, when it is remembered that the Saracens had at one time nearly possessed themselves of Aquitaine, and that, but for the successful valour of Charles Martel, Pepin, and Charlemagne, the crescent might have dispossessed the cross of the fairest portion of Europe. The fervent sentiments of devotion which direct men's eyes toward heaven, were then justly invoked, to unite with those which are most valuable on earth—the love of our country and its liberties.

But the Romish clergy, who have in all ages possessed the wisdom of serpents, if they sometimes have fallen short of the simplicity of doves, saw the advantage of converting this temporary zeal, which animated the warriors of their creed against the invading infidels, into a permanent union of principles, which should blend the ceremonies of religious worship with the military establishment of the ancient Goths and Germans. The admission of the noble youth to the practice of arms was no longer a mere military ceremony, where the sword or javelin was delivered to him in presence of the prince or elders of his tribe; it became a religious rite, sanctified by the forms of the church, which he was in future to defend. The novice had to watch his arms in a church or chapel, or at least on hallowed ground, the night before he had received the honour of knighthood. He was made to assume a white dress, in imitation of the Neophytes of the church. Fast and confession were added to vigils, and the purification of the bath was imposed on the military acolyte, in imitation of the initiatory rite of Christianity; and he was attended by godfathers, who became security for his performing his military vows, as sponsors had formerly appeared for him at baptism. In all points of ceremonial, the investiture of chivalry was brought to resemble, as nearly as possible, the administration of the sacraments of the church. The ceremony itself was performed, where circumstances would admit, in a church or cathedral; and the weapons with which the young warrior was invested were previously blessed by the priest. The oath of chivalry bound the knight to defend the rights of the holy church, to respect religious persons and institutions, and to obey the precepts of the gospel. Nay more, so intimate was the union betwixt chivalry and religion supposed to be, that the several gradations of the former were seriously considered as parallel to those of the church, and the knight was supposed to resemble the bishop in rank, duties, and privileges. At what period this complete infusion of religious ceremonial into an order purely military first commenced, and when it became complete and perfect, would be a curious but a difficult subject of investigation. Down to the reign of Charlemagne, and somewhat lower, the investiture was of a nature purely civil; but long before the time of the crusades, it had assumed the religious character we have described.

The effect which this union of religious and military zeal was like to produce in every other case save that of defensive war, could not but be unfavourable to the purity of the former. The knight, whose profession was war, being solemnly enlisted in the service of the gospel of peace, regarded infidels and heretics of every description as the enemies whom, as God's own soldier, he was called upon to attack and slay wherever he could meet with them, without demanding or waiting for any other cause of quarrel than the difference of religious faith. The duties of morality were indeed formally imposed on him by the oath of his order, as well as that of defending the church and extirpating heresy and misbelief. But in all ages it has been usual for men to compound with their consciences for breaches of the moral code of religion, by a double proportion of zeal for its abstract doctrines. In the middle ages, this course might be pursued on system; for the church allowed an exploit done on the infidels as a merit which might obliterate the guilt of the most atrocious crimes.

The genius alike of the age and of the order tended to render the zeal of the professors of chivalry fierce, burning, and intolerant. If an infidel, says a great authority, impugn the doctrines of the Christian faith before a churchman, he should reply to him by argument; but a knight should render no other reason to the infidel than six inches of his falchion thrust into his accursed bowels. Even courtesy, and the respect due to ladies of high degree, gave way when they chanced to be infidels. The renowned Sir Bevis of Hamptoun, being invited by the fair Princess Josiane to come to her bower, replies to the paymims who brought the message,

> I will ne gou one foot on ground
> For to speke with an heathen hound;
> Unchristen houndes, I rede ye flee,
> Or I your hearte's bloode will see.

This intemperate zeal for religion the knights were expected to maintain at every risk, however imminent. Like the early Christians, they were prohibited from acquiescing, even by silence, in the rites of idolatry, although death should be the consequence of their interrupting them. In the fine romance of *Huon of Bourdeaux*, that champion is represented as having failed in duty to God and his faith, because he had professed himself a Saracen, for the temporary purpose of obtaining entrance into the palace of the Amial Gaudifer. "And when Sir Huon passed the third gate, he remembered him of the lie he had spoken to obtain entrance into the first. Alas! said the knight, what but destruction can betide one who has so foully falsified and denied his faith towards him who has done so much for me!" His mode of repentance was truly chivalrous. When he came to the gate of the last interior inclosure of the castle, he said to the warder, "Pagan, accursed be thou of God, open the gate." When he entered the hall where the Pagan monarch was seated in full state, he struck off, without ceremony, the head of the Pagan lord who sat next in rank to him, exclaiming at the same time, with a loud voice, "God, thou hast given me grace well to commence my emprize; may our Redeemer grant me to bring it to an honourable conclusion." Many such passages might be quoted, to show the nature of the zeal which was supposed to actuate a Christian knight; but it is needless to ransack works of fiction for this purpose. The real history of the crusades, founded on the spirit of chivalry, and on the restless and intolerant zeal which was blended by the churchmen with this military establishment, are an authentic and fatal proof of the same facts. The hairbrained and adventurous character of these enterprises, not less than the promised pardons, indulgences,

and remissions of the church, rendered them dear to the warriors of the middle ages; the idea of re-establishing the Christian religion in the Holy Land, and wresting the tomb of Christ from the infidels, made kings, princes, and nobles, blind to its hazards; and they rushed, army after army, to Palestine, in the true spirit of chivalry, whose faithful professors felt themselves the rather called upon to undertake an adventure, from the peculiar dangers which surrounded it, and the numbers who had fallen in previous attempts.

It was after the conquest of the Holy Land that the union between temporal and spiritual chivalry (for such was the term sometimes given to monastic institutions) became perfect, by the institution of the two celebrated military orders of monks, the knights templars and knights of St John of Jerusalem, who, renouncing (at least in terms) the pomp, power, and pleasures of the world, and taking upon themselves the monastic vows of celibacy, purity, and obedience, did not cease to remain soldiers, and directed their whole energy against the Saracens. The history of these orders will be found in its proper place in this work; but their existence is here noticed, as illustrating our general proposition concerning the union of devotion and chivalry. A few general remarks will close this part of the subject.

The obvious danger of teaching a military body to consider themselves as missionaries of religion, and bound to spread its doctrines, is, that they are sure to employ in its service their swords and lances. The end is held to sanctify the means, and the slaughter of thousands of infidels is regarded as an indifferent, or rather as a meritorious action, providing it may occasion the conversion of the remnant, or the peopling of their land with professors of a purer faith. The wars of Charlemagne in Saxony, the massacres of the Albigenses in the south of France, the long-continued wars of Palestine, all served to illustrate the dangers resulting from the doctrine which inculcated religion, not as a check upon the horrors and crimes of war, but as itself its most proper and legitimate cause. The evil may be said to have survived the decay of chivalry, to have extended itself to the new world, and to have occasioned those horrors with which it was devastated for ages after its first discovery. The Spanish conquerors of South America were not, indeed, knights-errant; but the nature of their enterprises, as well as the mode in which they were conducted, partook deeply of the spirit of chivalry. In no country of Europe had this spirit sunk so deeply and spread so wide as in Spain. The extravagant positions respecting the point of honour, and the romantic summons which chivalry proclaimed to deeds of danger and glory, suited the ardent and somewhat oriental character of the Spaniards, a people more remarkable for force of imagination and depth of feeling than for wit and understanding. Chivalry, in Spain, was embittered by a double proportion of intolerant bigotry, owing to their constant and inveterate wars with the Moorish invaders. The strain of sentiment, therefore, which chivalry inspired, continued for a long time to mark the manners of Spain, after the decay of its positive institutions, as the beams of the sun tinge the horizon after the setting of his orb. The warriors whom she sent to the new world sought and found marvels which resembled those of romance; they achieved deeds of valour against such odds of numbers as are only recorded in the annals of knight-errantry; and, alas! they followed their prototypes in that indifference for human life, which is the usual companion of intolerant zeal. Avarice, indeed, brought her more sordid shades to complete the gloomy picture; and avarice was unknown to the institutions of chivalry. The intolerant zeal, however, which overthrew the altars of the Indians by violence, instead of assailing their errors by reason, and which imputed to them as crimes their ignorance of a religion which had never been preached to them, and their rejection of speculative doctrines of faith, propounded by persons whose practice was so ill calculated to recommend them,—all these may be traced to the spirit of chivalry, and the military devotion of its professors.

The religion of the knights, like that of the times, was debased by superstition. Each champion had his favourite saint, to whom he addressed himself upon special occasions of danger, and to whom, after the influence of his lady's eyes, he was wont to ascribe the honour of his conquests. St Michael, the leader of banded Seraphim, and the personal antagonist of Satan,—St George, St James, and St Martin, all of whom popular faith had invested with the honours of chivalry,—were frequently selected as the appropriate champions of the militant adventurers yet on earth. The knights used their names adjected to their own as their insignia, watchword, or signal for battle. Edward III. fighting valiantly in a night-skirmish before the gates of Calais, was heard to accompany each blow he struck with the invocation of his tutelar saints, Ha! Saint Edward! ha! Saint George! But the Virgin Mary, to whom their superstition ascribed the qualities of youth, beauty, and sweetness, which they prized in their terrestrial mistresses, was an especial object of the devotion of the followers of chivalry, as of all other good Catholics. Tournaments were undertaken, and feats of arms performed, in her honour, as in that of an earthly mistress; and the veneration with which she was regarded seems occasionally to have partaken of the character of romantic affection. She was often held to return this love by singular marks of her favour and protection. During an expedition of the Christians to the coast of Africa, Froissart informs us that a large black dog was frequently seen in their camp, which barked furiously whenever the infidels approached it by night, and rendered such service to the Christian adventurers by its vigilance, that with one consent they named it "the dog of our lady."

But although, as is incidental to human institutions, the mixture of devotion in the military character of the knight degenerated into brutal intolerance and superstition in its practical effects, nothing could be more beautiful and praiseworthy than the theory on which it was grounded. That the soldier drawing the sword in defence of his country and its liberties, or of the oppressed innocence of damsels, widows, and orphans, or in support of religious rights, for which those to whom they belonged were disqualified by their profession to combat in person,—that he should blend with all the feelings which these offices inspired, a deep sense of devotion, exalting him above the advantage and even the fame which he himself might derive from victory, and giving dignity to defeat itself, as a lesson of divine chastisement and humiliation,—that the knight on whose valour his countrymen were to rely in danger, should set them an example in observing the duties and precepts of religion,—are circumstances so well qualified to soften, to dignify, and to grace the profession of arms, that we cannot but regret their tendency to degenerate into a ferocious propensity to bigotry, persecution, and intolerance. Such, however, is the tendency of all human institutions, which, however fairly framed in theory, are in practice corrupted by our evil passions, until the results which flow from them become the very reverse of what was to have been expected and desired.

The next ingredient in the spirit of chivalry, second in force only to the religious zeal of its professors, and frequently predominating over it, was a devotion to the female sex, and particularly to her whom each knight selected as the chief object of his affection, of a nature so ex-

travagant and unbounded as to approach to a sort of idolatry.

The original source of this sentiment is to be found, like that of chivalry itself, in the customs and habits of the northern tribes, who possessed, even in their rudest state, so many honourable and manly distinctions over all the other nations in the same stage of society. The chaste and temperate habits of these youth, and the opinion that it was dishonourable to hold sexual intercourse until the twentieth year was attained, was in the highest degree favourable, not only to the morals and health of the ancient Germans, but must have contributed greatly to place the females in that dignified and respectable rank which they held in society. Nothing tends so much to blunt the feelings, to harden the heart, and to destroy the imagination, as the worship of the Vaga Venus in early youth. Wherever women have been considered as the early, willing, and accommodating slaves of the voluptuousness of the other sex, their character has become degraded, and they have sunk into domestic drudges and bondswomen among the poor,—the slaves of a haram among the more wealthy. On the other hand, the men, easily and early sated with indulgences, which soon lose their poignancy when the senses only are interested, become first indifferent, then harsh and brutal, to the unfortunate slaves of their pleasures. The sated lover,—and perhaps it is the most brutal part of humanity,—is soon converted into the capricious tyrant, like the successful seducer of the modern poet.

> Hard! with their fears and terrors to behold
> The cause of all, the faithless lover cold,
> Impatient grown at every wish denied,
> And barely civil, soothed and gratified.
>
> Crabbe's *Borough*, p. 213.

Habitual indulgence seeks change of objects to relieve satiety. Hence polygamy, and all its brutalizing consequences, which were happily unknown to our Gothic ancestors. The virtuous and manly restraints imposed on their youth were highly calculated to exalt the character of both sexes, and especially to raise the females in their own eyes and those of their lovers. They were led to regard themselves, not as the passive slaves of pleasure, but as the objects of a prolonged and respectful affection, which could only be finally gratified when their lovers had attained the age of mature reason, and were capable to govern and to defend the family which should arise around them. With the young man imagination and sentiment combined to heighten his ideas of a pleasure which nature instructed him to seek, and which the wise laws of his country prevented him from prematurely aspiring to share. To a youth so situated, the maiden on whom he placed his affections became an object of awe as well as of affection; the passion which he indulged for her was of a nature as timid and pure as engrossing and powerful; the minds of the parties became united before the joining of their hands, and a moral union preceded the mere intercourse of the sexes.

The marriages formed under these happy auspices were in general happy and affectionate. Adultery was unfrequent, and punished with the utmost rigour. Nor could she who had undergone the penalty of such a crime find a second husband, however distinguished by beauty, birth, or wealth. (Taciti *Germania.*) The awe and devotion with which the lover had regarded his destined bride during the years in which the German youth were enjoined celibacy, became regard and affection in the husband towards the sharer of his labours and the mistress of his household. The matron maintained that rank in society which love had assigned to the maiden. No one, then, says the Roman historian, dared to ridicule the sacred union of marriage, or to term an infringement of its laws a compliance with the manners of the age. The German wife, once married, seldom endeavoured to form a second union, but continued, in honoured widowhood, to direct and manage the family of her deceased husband. This habitual subjection of sensuality to sentiment, these plain, simple, virtuous, and temperate manners of the German females, placed the females in that high rank of society which the sex occupies when its conduct is estimable, and from which it as certainly declines in ages or climates prone to luxurious indulgence. The superintendence of the domestic affairs was assigned to the German women, a duty in which the men seldom interfered, unless when rendered by age or wounds incapable of warfare. They were capable of exercising the supreme authority in their tribe, and of holding the honours of the priesthood. But the influence of the women in a German tribe, as well as their duties in war, will be best understood from the words of Tacitus. "It is the principal incitement to the courage of the Germans, that in battle their separate troops or columns are not arranged promiscuously as chance directs, but consist each of a united family or clan with its relatives. Their dearest pledges are placed in the vicinity, whence may be heard the cries of their females, the wailings of their infants, whom each accounts the most sacred witnesses and the dearest eulogists of his valour. The wounded repair to their mothers and spouses, who hesitate not to number their wounds, and to suck the blood that flows from them. The females carry refreshment to those engaged in the contest, and encourage them by their exhortations. It is related that armies, when disordered and about to give way, have renewed the contest at the instance of the women, moved by the earnestness of their entreaties, their exposed bosoms, and the danger of approaching captivity; a doom which they dread more on account of their females than even on their own, insomuch that these German states are most effectually bound to obedience, among the number of whose hostages there are a number of noble damsels as well as men. They deem, indeed, that there resides in the female sex something sacred and capable of presaging the future; nor do they scorn their advice or neglect their responses. In the time of Vespasian we have seen Velleda long hold the rank of a deity in most of the German states; and, in former times, they venerated Aurinia and other females; not, however, from mere flattery, nor yet in the character of actual goddesses." The tales and *Sagas* of the north, in which females often act the most distinguished part, might also be quoted as proofs of the rank which they held in society. We find them separating the most desperate frays by their presence, their commands, or their mantles, which they threw over the levelled weapons of the combatants. Nor were their rights less extensive than their authority. In the *Eyrbiggia Saga* we are informed that Thordisa, the mother of the celebrated Pontiff Snorro, and wife of Biarko of Stelgafels, received a blow from her husband. The provocation was strong; for the matron had, in her husband's house and at his table, attempted to stab his guest Eyalf Graie, on account of his having slain one of her relations. Yet so little did this provocation justify the offence, that, in the presence of the comitia, or public assembly of the tribe, Thordisa invoked witnesses to bear testimony that she divorced her husband on account of his having raised his hand against her person. And such were the rights of a northern *mater-familias*, that the divorce and a division of goods immediately took place between the husband and wife, although the violence of which Thordisa complained was occasioned by her own attempt to murder a guest.

We have traced the ideas of the Gothic tribes on this

important point the more at length, because they show that the character of veneration, sanctity, and inviolability attached to the female character, together with the important part assigned to them in society, were brought with them from their native forests, and had existence long before the chivalrous institutions in which they made so remarkable a feature. They easily became amalgamated in a system so well fitted to adopt whatever was romantic and enthusiastic in manners or sentiment. Amid the various duties of knighthood, that of protecting the female sex, respecting their persons, and redressing their wrongs, becoming the champion of their cause, and the chastiser of those by whom they were injured, was presented as one of the principal objects of the institution. Their oath bound the new-made knights to defend the cause of all women without exception; and the most pressing way of conjuring them to grant a boon was to implore it in the name of God and the ladies. The cause of a distressed lady was, in many instances, preferable to that even of the country to which the knight belonged. Thus, the Captal de Buche, though an English subject, did not hesitate to unite his troops with those of the Compte de Foix, to relieve the ladies in a town where they were besieged and threatened with violence by the insurgent peasantry. The looks, the words, the sign of a lady, were accounted to make knights at time of need to perform double their usual deeds of strength and valour. At tournaments and in combats the voices of the ladies were heard, like those of the German females in former battles, calling on the knights to remember their fame, and exert themselves to the uttermost. "Think, gentle knights," was their cry, "upon the wool of your breasts, the nerve of your arms, the love you cherish in your hearts, and do valiantly, for ladies behold you." The corresponding shouts of the combatants were, "Love of ladies! Death of warriors! On, valiant knights, for you fight under fair eyes."

Where the honour or love of a lady was at stake, the fairest prize was held out to the victorious knight, and champions from every quarter were sure to hasten to combat in a cause so popular. Chaucer, when he describes the assembly of the knights who came with Arcita and Palemon to fight for the love of the fair Emilie, describes the manners of his age in the following lines:

> For every knight that loved chivalry,
> And would his thankes have a passant name,
> Hath pray'd that he might ben of that game,
> And well was him that thereto chusen was;
> For if there fell to-morrow such a case,
> Ye knowen well that every lusty knight
> That loveth par amour, and hath his might,
> Were it in Engellonde, or elleswhere,
> They wold hir thankes willen to be there.
> To fight for a lady! Ah! Benedicite,
> It were a lusty sight for to see.

It is needless to multiply quotations on a subject so trite and well known. The defence of the female sex in general, the regard due to their honour, the subservience paid to their commands, the reverend awe and courtesy which, in their presence, forbear all unseemly words and actions, were so blended with the institution of chivalry, as to form its very essence.

But it was not enough that the "very perfect, gentle knight," should reverence the fair sex in general. It was essential to his character that he should select, as his proper choice, "a lady and a love," to be the polar star of his thoughts, the mistress of his affections, and the directress of his actions. In her service, he was to observe the duties of loyalty, faith, secrecy, and reverence. Without such an empress of his heart, a knight, in the phrase of the times, was a ship without a rudder, a horse without a bridle, a sword without a hilt; a being, in short, devoid of that ruling guidance and intelligence, which ought to inspire his bravery and direct his actions.

The Dame des Belles Cousines, having cast her eyes upon the little Jean de Saintré, then a page of honour at court, demanded of him the name of his mistress and his love, on whom his affections were fixed. The poor boy, thus pressed, replied, that the first object of his love was the lady his mother, and the next his sister Jacqueline. "Jouvencel," replied the inquisitive lady, who had her own reasons for not being contented with this simple answer, "we do not now talk of the affection due to your mother and sister; I desire to know the name of the lady whom you love *par amours*."—"In faith, madam," said the poor page, to whom the mysteries of chivalry, as well as of love, were yet unknown, "I love no one *par amours*."—"Ah, false gentleman, and traitor to the laws of chivalry," returned the lady, "dare you say that you love no lady? well may we perceive your falsehood and craven spirit by such an avowal. Whence were derived the great valour and the high achievements of Lancelot of Gawain, of Tristrem, of Giron the Courteous, and of other heroes of the Round Table,—whence those of Panthus, and of so many other valiant knights and squires of this realm, whose names I could enumerate had I time,—whence the exaltation of many whom I myself have known to arise to high dignity and renown, except from their animating desire to maintain themselves in the grace and favour of their ladies, without which mainspring to exertion and valour they must have remained unknown and insignificant. And do you, coward page, now dare to aver that you have no lady, and desire to have none? Hence, false heart that thou art." To avoid these bitter reproaches, the simple page named as his lady and love *par amours* Matheline de Coucy, a child of ten years old. The answer of the Dame des Belles Cousines, after she had indulged in the mirth which his answer prompted, instructed him how to place his affections more advantageously; and as the former part of the quotation may show the reader how essential it was to the profession of chivalry, that every one of its professors should elect a lady of his affections, that which follows explains the principles on which his choice should be regulated. "Matheline," said the lady, "is indeed a pretty girl, and of high rank, and better lineage than appertains to you. But what good, what profit, what honour, what advantage, what comfort, what aid, what council for advancing you in the ranks of chivalry, can you derive from such a choice? Sir, you ought to choose a lady of high and noble blood, who has the talent and means to counsel and aid you at your need; and her you ought to serve so truly, and love so loyally, that she must be compelled to acknowledge the true and honourable affection which you bear to her. For believe there is no lady, however cruel and haughty, but through length of faithful service will be brought to acknowledge and reward loyal affection with some portion of pity, compassion, or mercy. In this manner you will attain the praise of a worthy knight; and till you follow such a course, I would not give an apple for you or your achievements." The lady then proceeds to lecture the acolyte of chivalry at considerable length on the seven mortal sins, and the way in which the true amorous knight may eschew commission of them. Still, however, the saving grace inculcated in her sermon was fidelity and secrecy in the service of the mistress whom he should love *par amours*. She proves, by the aid of quotations from the Scripture, the fathers of the church, and the ancient philosophers, that the true and faithful lover can never fall into the crimes of Pride, Anger, Envy, Sloth, or Gluttony. From each of these his true faith is held to warrant and defend him. Nay, so pure was the nature of the flame which she recommended, that she maintained it

to be inconsistent even with the seventh sin of Chambering and Wantonness, to which it might seem too nearly allied. The least dishonest thought or action was, according to her doctrine, sufficient to forfeit the chivalrous lover the favour of his lady.' It seems, however, that the greater part of her charge concerning incontinence is levelled against such as haunted the receptacles of open vice; and that she reserved an exception (of which, in the course of the history, she made liberal use) in favour of the intercourse which, in all love, honour, and secrecy, might take place when the favoured and faithful knight had obtained, by long service, the boon of amorous mercy from the lady whom he loved *par amours*. The last encouragement which the Dame des Belles Cousines held out to Saintré, in order to excite his ambition, and induce him to fix his passion upon a lady of elevated birth, rank, and sentiment, is also worthy of being quoted, since it shows that it was the prerogative of chivalry to abrogate the distinctions of rank, and elevate the hopes of the knight, whose sole patrimony was his arms and valour, to the high-born and princely dame, before whom he carved as a sewer.

"How is it possible for me," replied poor Saintré, after having heard out the unmercifully long lecture of the Dame des Belles Cousines, "to find a lady, such as you describe, who will accept of my service, and requite the affection of such a one as I am?"—"And why should you not find her?" answered the lady preceptress. "Are you not gently born? Are you not a fair and proper youth? Have you not eyes to look on her—ears to hear her—a tongue to plead your cause to her—hands to serve her—feet to move at her bidding—body and heart to accomplish loyally her commands? And, having all these, can you doubt to adventure yourself in the service of any lady whatsoever?"

In these extracts are painted the actual manners of the age of chivalry. The necessity of the perfect knight having a mistress, whom he loved *par amours*, the duty of dedicating his time to obey her commands, however capricious, and his strength to execute extravagant feats of valour, which might redound to her praise,—for all that was done for her sake, and under her auspices, was counted her merit, as the victories of their generals were ascribed to the Roman emperors,—was not a whit less necessary to complete the character of a good knight than the Dame des Belles Cousines represented it.

It was the especial pride of each distinguished champion, to maintain against all others the superior worth, beauty, and accomplishments of his lady; to bear her picture from court to court, and support with lance and sword her superiority to all other dames, abroad or at home. To break a spear for the love of their ladies, was a challenge courteously given, and gently accepted, among all true followers of chivalry; and history and romance are alike filled with the tilts and tournaments which took place upon this argument, which was ever ready and ever acceptable. Indeed, whatever the subject of the tournament had been, the lists were never closed until a solemn course had been made in honour of the ladies.

There were knights yet more adventurous, who sought to distinguish themselves by singular and uncommon feats of arms in honour of their mistresses, and such was usually the cause of the whimsical and extravagant vows of arms which we have subsequently to notice. To combat against extravagant odds, to fight amid the press of armed knights without some essential part of their armour, to do some deed of audacious valour in face of friend and foe, were the services by which the knights strove to recommend themselves, or which their mistresses (very justly so called) imposed on them as proofs of their affection.

On such occasions the favoured knight, as he wore the colours and badge of the lady of his affections, usually exerted his ingenuity in inventing some device or cognisance which might express their affection, either openly, as boasting of it in the eye of the world, or in such mysterious mode of education as should only be understood by the beloved person, if circumstances did not permit an avowal of his passion. Among the earliest instances of the use of the English language at the court of the Norman monarchs, is the distich painted in the shield of Edward III. under the figure of a white swan, being the device which that warlike monarch wore at a tourney at Windsor.

Ha! ha! the white swan,
By God his soul, I am thy man.

The choice of these devices was a very serious matter; and the usurpation of such as any knight had previously used and adopted was often the foundation of a regular quarrel, of which many instances occur in Froissart and other writers.

The ladies, bound as they were in honour to requite the passion of their knights, were wont on such occasions to dignify them by the present of a scarf, ribbon, or glove, which was to be worn in the press of battle and tournament. These marks of favour they displayed on their helmets, and they were accounted the best incentives to deeds of valour. The custom appears to have prevailed in France to a late period, though polluted with the grossness so often mixed with the affected refinement and gallantry of that nation. In the attack made by the Duke of Buckingham upon the Isle of Rhé, favours were found on the persons of many of the French soldiers who fell at the skirmish on the landing; but for the manner in which they were disposed we are compelled to refer to Howel and Wilson.

Sometimes the ladies, in conferring these tokens of their favour, clogged them with the most extravagant and severe conditions. But the lover had this advantage in such cases, that if he ventured to encounter the hazard imposed, and chanced to survive it, he had, according to the fashion of the age, the right of exacting from the lady favours corresponding in importance. The annals of chivalry abound with stories of cruel and cold fair ones who subjected their lovers to extremes of danger, in hopes that they might get rid of their addresses, but were, upon their unexpected success, caught in their own snare, and, as ladies who would not have their name made the theme of reproach by every minstrel, compelled to recompense the deeds which their champion had achieved in their name. There are instances in which the lover used his right of reprisals with some rigour, as in the well-known *fabliau* of the three knights and the shift, in which a lady proposes to her three lovers successively the task of entering unarmed into the melée of a tournament, arrayed only in one of her shifts. The perilous proposal is declined by two of the knights, and accepted by the third, who thrusts himself, in the unprotected state required, into all the hazards of the tournament, sustains many wounds, and carries off the prize of the day. On the next day the husband of the lady (for she was married) was to give a superb banquet to the knights and nobles who had attended the tourney. The wounded victor sends the shift back to its owner, with his request that she would wear it over her rich dress on this solemn occasion, soiled and torn as it was, and stained all over with the blood of its late wearer. The lady did not hesitate to comply, declaring that she regarded this shift, stained with the blood of her "fair friend, as more precious than if it were of the most costly materials." Jaques de Basin, the minstrel,

who relates this curious tale, is at a loss to say whether the palm of true love should be given to the knight or to the lady on this remarkable occasion. The husband, he assures us, had the good sense to seem to perceive nothing uncommon in the singular vestment with which his lady was attired, and the rest of the good company highly admired her courageous requital of the knight's gallantry.

Sometimes the patience of the lover was worn out by the cold-hearted vanity which thrust him on such perilous enterprises. At the court of one of the German emperors, while some ladies and gallants of the court were looking into a den where two lions were confined, one of them purposely let her glove fall within the palisade which inclosed the animals, and commanded her lover, as a true knight, to fetch it out to her. He did not hesitate to obey; jumped over the inclosure; threw his mantle towards the animals as they sprung at him; snatched up the glove, and regained the outside of the palisade. But when in safety, he proclaimed aloud, that what he had achieved was done for the sake of his own reputation, and not for that of a false lady, who could for her sport and cold-blooded vanity face a brave man on a duel so desperate; and, with the applause of all that were present, he renounced her love for ever.

This, however, was an uncommon circumstance. In general, the lady was supposed to have her lover's character as much at heart as her own, and to mean, by pushing him upon enterprises of hazard, only to give him an opportunity of meriting her good graces, which she could not with honour confer upon one undistinguished by deeds of chivalry. An affecting instance is given by Godscroft.

At the time when the Scotch were struggling to recover from the usurpation of Edward I., the castle of Douglas was repeatedly garrisoned by the English, and these garrisons were as frequently surprised and cut to pieces by the good Lord James of Douglas, who, lying in the mountainous wilds of Cairntable, and favoured by the intelligence which he maintained among his vassals, took opportunity of the slightest relaxation of vigilance to surprise the fortress. At length a fair dame of England announced to the numerous suitors who sought her hand, that she would confer it on the man who should keep the perilous castle of Douglas (so it was called) for a year and a day. The knight who undertook this dangerous task at her request discharged his duty like a careful soldier for several months, and the lady relenting at the prospect of his continued absence, sent a letter to recal him, declaring she held his probation as accomplished. In the meantime, however, he had received a defiance from Douglas, threatening him, that, let him use his utmost vigilance, he would recover from him his father's castle before Palm-Sunday. The English knight deemed that he could not in honour leave the castle till this day was past; and on the very eve of Palm-Sunday was surprised and slain with the lady's letter in his pocket, the perusal whereof greatly grieved the good Lord James of Douglas.

We are left much to our own conjectures on the appearance and manners of these haughty beauties, who were wooed with sword and lance, whose favours were bought at the expense of such dear and desperate perils, and who were worshipped, like heathen deities, with human sacrifices. The character of the ladies of the ages of chivalry was probably determined by that of the men, to whom it sometimes approached. Most of these heroines were educated to understand the treatment of wounds, not only of the heart, but of the sword; and, in romance at least, the quality of leech-craft (practised by the Lady Bountifuls of the last generation) was essential to the character of an accomplished princess. They sometimes trespassed on the province of their lovers, and actually took up arms. The Countess de Montfort in Bretagne is celebrated by Froissart for the gallantry with which she defended her castle when besieged by the English; and the old prior of Lochleven in Scotland is equally diffuse in the praise of Black Agnes, countess of March, who, in the reign of Edward III. held out the castle of Dunbar against the English. She appeared on the battlements with a white handkerchief in her hands, and wiped the walls in derision where they had been struck by stones from the English engines. When Montague, earl of Salisbury, brought up to the walls a military engine, like the Roman *estudo*, called a sow, she exclaimed in rhime,

Beware Montagou,
For farrow shall thy sow.

A huge rock discharged from the battlements dashed the sow to pieces, and the English soldiers who escaped from its ruins were called by the countess, in derision, Montague's pigs.

The nature of the conferences between these high-minded heroines and their lovers was somewhat peculiar. Their delectations were in tales of warlike exploits, and in discourse of hunting and hawking. But when these topics were exhausted, they found in metaphysical discussions of nice questions concerning the passion of love, an endless source of interesting disquisition. The idea and definition of a true and pure passion, illustrated by an hundred imaginary cases devised on purpose, were managed in the same manner in which the schoolmen of the day agitated their points of metaphysical theology. The Scotists and the Thomists, whose useless and nonsensical debates cumbered the world with so many volumes of absurd disquisition upon the most extravagant points of polemical divinity, saw their theological labours rivalled in the courts of love, where the most abstract reasoning was employed in discussing subtile questions upon the exaggerated hopes, fears, doubts, and suspicions of lovers, the circumstances of whose supposed cases were often ridiculous, sometimes criminal, sometimes licentious, and almost always puerile and extravagant. These particulars will fall to be more fully illustrated under the article Troubadour. In the meanwhile, it is sufficient to state, that the discussions in the courts of love regarded such important and interesting questions as, Whether his love be most meritorious who has formed his passion entirely on hearing, or his who has actually seen his mistress? with others of a tendency equally edifying.

Extremes of every kind border on each other; and as the devotion of the knights of chivalry degenerated into superstition, the Platonic refinements and subtilties of amorous passion which they professed were sometimes compatible with very coarse and gross debauchery. We have seen that they derived from the Gothic tribes that high and reverential devotion to the female sex which forms the strongest tint in the manners of chivalry. But with the simplicity of these ancient times they lost their innocence; and woman, though still worshipped with enthusiasm, as in the German forests, did not continue to be (in all cases at least) the same pure object of worship. The marriage-tie ceased to be respected; and as the youthful knights had seldom the means or inclination to encumber themselves with wives and families, their lady-love was often chosen among the married ladies of the court. It is true, that such a connection was supposed to be consistent with all respect and honour, and was regarded by the world, and sometimes by the husband, as a high strain of Platonic sentiment, through which the character of its object in no respect suffered. But nature vindicated herself for the violence offered to her; and while the metaphysical students and pleaders in the courts of love professed to aspire but to the lip or hand of their ladies,

and to make a merit of renouncing all farther intrusion on their bounties, they privately indulged themselves in loves which had very little either of delicacy or sentiment. In the romance of the *Petit Jehan de Saintré*, that self-same Lady des Belles Cousines, who lectures so learnedly upon the seven mortal sins, not only confers on her deserving lover "le don d'amoureux merci," but enters into a very unworthy and disgraceful intrigue with a stout broad-shouldered abbot, into which no sentiment whatever can be supposed to enter. The romance of *Tirante the White*, praised by Cervantes as a faithful picture of the knights and ladies of his age, seems to have been written in an actual brothel, and, contrasted with others, may lead us to suspect that their purity is that of romance, its profligacy that of reality. This license was greatly increased by the crusades, from which the survivors of these wild expeditions brought back the corrupted morals of the East, to avenge the injuries they had inflicted on its inhabitants. Joinville has informed us of the complaints which Saint Louis made to him in confidence, of the debaucheries practised in his own royal tent, by his attendants, in this holy expedition. And the ignominious punishment to which he subjected a knight, detected in such excesses, shows what severe remedies he judged necessary to stem the increase of libertinism.

Indeed, the gross license which was practised during the middle ages may be well estimated by the vulgar and obscene language that was currently used in tales and fictions addressed to the young and noble of both sexes. In the romance of the *Round Table*, as Ascham sternly states, little was to be learned but examples of homicide and adultery, although he had himself seen it admitted to the antichamber of princes, when it was held a crime but to be possessed of the word of God. In the romance of *Amadis de Gaul*, and many others, the heroines, without censure or imputation, confer on their lovers the rights of a husband before the ceremony of the church gave them a title to the name. These are serious narrations, in which decorum, at least, is rarely violated; but the comic tales are of a grosser cast.

The *Canterbury Tales* of Chaucer contain many narratives, of which not only the diction, but the whole turn of the narrative, is extremely gross. Yet it does not seem to have occurred to the author, a man of rank and fashion, that they were improper to be recited, either in the presence of the prioress and her votaries, or in that of the noble knight who

> ——— of his port was meek as is a maid,
> And never yet no villany he said.

And he makes but a light apology for including the disasters of the *Millar of Trompington*, or of *Absalom the Gentle Clerk*, in the same series of narrations with the *Knight's Tale*. Many of Bandello's most profligate novels are expressly dedicated to females of rank and consideration; and, to conclude, the *Fabliaux*, published by Barbazan and Le Grand, are frequently as revolting, from their naked grossness, as interesting from the lively pictures which they present of life and manners. Yet these were the chosen literary pastimes of the fair and the gay, during the times of chivalry, listened to, we cannot but suppose, with an interest considerably superior to that exhibited by the yawning audience who heard the theses of the courts of love attacked and supported in logical form, and with metaphysical subtilty.

Should the manners of the times appear inconsistent in these respects which we have noticed, we must remember that we are ourselves variable and inconsistent animals, and that, perhaps, the surest mode of introducing and encouraging any particular vice, is to rank the corresponding virtue at a pitch unnatural in itself, and beyond the ordinary attainment of humanity. The vows of celibacy introduced profligacy among the Catholic clergy, as the high-flown and overstrained Platonism of the professors of chivalry favoured the increase of license and debauchery.

After the love of God and of his lady, the *preux chevalier* was to be guided by that of glory and renown. He was bound by his vow to seek out adventures of risk and peril, and never to abstain from the quest which he might undertake, for any unexpected odds of opposition which he might encounter. It was not indeed the sober and regulated exercise of valour, but its fanaticism, which the genius of chivalry demanded of its followers. Enterprises the most extravagant in conception, the most difficult in execution, the most useless when achieved, were those by which an adventurous knight chose to distinguish himself. There were solemn occasions also on which these displays of chivalrous enthusiasm were specially expected and called for. It is only sufficient to name the tournaments, single combats, and solemn banquets, at which vows of chivalry were usually formed and proclaimed.

The tournaments were uniformly performed and frequented by the choicest and noblest youth in Europe, until the fatal accident of Henry II. after which they fell gradually into disuse. It was in vain that, from the various accidents to which they gave rise, these dangerous amusements were prohibited by the heads of the Christian church. The popes, infallible as they were deemed, might direct, but could not curb, the military spirit of chivalry; they could excite crusades, but they could not abolish tournaments. Their laws, customs, and regulations, will fall properly under a separate article. It is here sufficient to observe, that these military games were of two kinds. In the most ancient, meaning "nothing in hate, but all in honour," the adventurous knights fought with sharp swords and lances as in the day of battle. Even then, however, the number of blows was usually regulated, or, in case of a general combat, some rules were laid down to prevent too much slaughter. The regulations of Duke Theseus for the tournament in Athens, as narrated by Chaucer in the *Knight's Tale*, may give a good example of these restrictions. When the combatants fought on foot, it was prohibited to strike otherwise than at the head or body; the number of strokes to be dealt with the sword and battle-axe were carefully numbered and limited, as well as the careers to be run with the lance. In these circumstances alone, the combats at *outrance*, as they were called, differed from encounters in actual war.

In process of time, the dangers of the solemn justs, held under the authority of princes, were modified by the introduction of arms of courtesy, as they were termed, lances, namely, without heads, and with round braces of wood at the extremity called *rockets*, and swords without points, and with blunted edges. But the risk continued great from bruises, falls, and the closeness of the defensive armour of the times, in which the wearers were often smothered. The weapons at *outrance* were afterwards chiefly used when knights of different and hostile countries engaged by appointment, or when some adventurous gallants took upon them the execution of an enterprise of arms (*pas d'armes*), in which they, as challengers, undertook, for a certain time, and under certain conditions, to support the honour of their country or their mistress against all comers. These enterprises often ended fatally, but the knights who undertook them were received in the foreign countries which they visited in accomplishment of their challenge, with the highest deference and honour; their arrival was considered as affording a sub-

Chivalry

ject of sport and jubilee to all ranks; and when any mischance befel them, such as that of De Lindsay, who, in a tournament at Berwick, had his helmet nailed to his skull, by the truncheon of a lance which penetrated both, and died after devoutly confessing himself in the casque from which they could not disengage him, the knights who looked on prayed that God would vouchsafe them in his mercy a death so fair and so honourable. Stories of such challenges, with the minute details of the events of the combat, form frequent features in the histories of the age.

The contests of the tournament and the pas d'armes were undertaken merely in sport, and for thirst of honour. But the laws of the period afforded the adventurous knight other and more serious combats, in which he might exercise his valour. The custom of trying all doubtful cases by the body of a man, or, as it was otherwise expressed, by the judgment of God—in plain words, by referring the decision to the issue of a duel, prevailed universally among the Gothic tribes, from the highest antiquity. A *salvo* was devised for the obvious absurdity of calling upon the weak to encounter the strong, a churchman to oppose a soldier, or age to meet in the lists with activity and youth. It was held that either party might appear personally, or by his champion. This sage regulation gave exercise for the valour of the knights, who were bound by their oaths to maintain the cause of those who had no other protector. And, indeed, there is good reason to think that the inconveniences and injustice of a law so absurd in itself as that of judicial combat, were evaded and mitigated by the institutions of chivalry, since, among the number of knights who were eagerly hunting after opportunities of military distinction, a party incapable of supporting his own cause by combat could have little difficulty in finding a formidable substitute; so that no one, however bold and confident, could prosecute an unjust cause to the uttermost, without the risk of encountering some champion of the innocent party from among the number of hardy knights who traversed every country seeking ostensible cause of battle.

Besides these formal combats, it was usual for the adventurous knight to display his courage by stationing himself at some pass in a forest, on a bridge, or elsewhere, compelling all passengers to avouch the superiority of his own valour, and the beauty of his mistress, or otherwise to engage with him in single combat. When Alexius Comnenus received the homage of the crusaders, seated upon his throne, previous to their crossing the Hellespont, during the first crusade, a French baron seated himself by the side of the emperor of the East. He was reproved by Baldwin, and answered in his native language, "what ill-taught clown is this, who dares to keep his seat when the flower of the European nobility are standing around him!" The emperor, dissembling his indignation, desired to know the birth and condition of the audacious Frank. "I am," replied the baron, "of the noblest race of France. For the rest, I only know that there is near my castle a spot where four roads meet, and near it a church where men, desirous of single combat, spend their time in prayer till some one shall accept their challenge. Often have I frequented that chapel, but never met I one who durst accept my defiance." Thus the bridge of Rodomont, in the Orlando Furioso, and the valiant defiance which the knight of La Mancha hurled against the merchants of Toledo, who were bound to the fairs of Murcia, were neither fictions of Ariosto nor Cervantes, but had their prototypes in real story. The chivalrous custom of defying all and sundry to mortal combat subsisted in the borders until the days of Queen Elizabeth, when the worthy Bernard Gilpin found in his church of Houghton le Spring a glove hung over the altar, which he was informed indicated a challenge to all who should take it down. The remnants of the judicial combats, and the enterprises of arms, may be found in the duels of the present day. In former days they still more resembled each other; for, in the seventeenth century, not only the seconds on each side regularly engaged, but it was usual to have more seconds, even to the number of five or six; a custom pleasantly ridiculed by Lord Chesterfield in one of the papers of *The World*. It is obvious that an usage at once so ridiculous and so detrimental to the peace and happiness of society must give way, in proportion to the progress of common sense. The custom is in general upon the wane, even as far as respects single combat between men who have actually given or taken offence at each other. The general rules of good-breeding prevent causes of such disagreement from arising in the intercourse of society; and the forward duellist, who is solicitous in seeking them out, is generally accounted a vulgar and ferocious, as well as a dangerous character. At the same time, the habits derived from the days of chivalry still retain a striking effect on our manners, and have fully established a graceful as well as useful punctilio, which tends on the whole to the improvement of society. Every man is under the impression, that neither his strength, his wealth, his station, nor his wit, will excuse him from answering, at the risk of his life, any unbecoming encroachment on the civility due to the weakest, the poorest, the least important, or the most modest member of the society in which he mingles. All too in the rank and station of gentlemen are forcibly called upon to remember that they must resent the imputation of a voluntary falsehood as the most gross injury; that the rights of the weaker sex demand protection from every one who would hold a good character in society. In short, from the wild and overstrained courtesies of chivalry has been derived our present system of manners. It is not certainly faultless, and it is guarded by penalties which we must often regret as disproportionably severe. Yet it has a grace and dignity unknown to classic times, when women were slaves, and men coarse and vulgar, or overbearing and brutal, as suited their own humour, without respect to that of the rest of society.

II. Such being the tone and spirit of chivalry, derived from love, devotion, and valour, we have next to notice the special forms and laws of the order, which will be found to correspond in every respect to the spirit which they were designed to foster.

Rules and forms of chivalry.

The education of the future knight began at an early period. The care of the mother, after the first years of early youth were past, was deemed too tender, and the indulgences of the paternal roof too effeminate, for the future aspirant to the honours of chivalry. "Do you not bless God," said the Lady Mabel to her husband, the noble Duke Guerin of Montglaive, as on a solemn feast they looked on their four hopeful sons, "do you not bless God, that has given you such a promising issue?" "Dame," replied Guerin, in the true spirit of the age, "so help me God and Saint Martin! nothing can do me greater despite than to look on these four great lurdanes, who, arrived at such an age, yet do nothing but eat the fat, and drink the sweet, and spend their time in idle amusement."[1] To counteract these habits of indulgence, the first step to the order of knighthood was the degree of PAGE.

[1] *L'Hystoire de Guerin de Montglaive.*

Chivalry.

The page.

The young and noble stripling, generally about his twelfth year, was transferred from his father's house to that of some baron or noble knight, sedulously chosen by the anxious parent as that which had the best reputation for good order and discipline. The children of the first nobles and high crown vassals were educated by the royal court. And, however the reins of discipline might be in particular cases relaxed, or become corrupted in latter days, the theory was uniformly excellent. The youth, who was to learn modesty, obedience, and address in arms and horsemanship, was daily exercised in the use of arms, beginning with such as were suited to his strength. He was instructed how to manage a horse with grace and dexterity; how to use the bow and the sword; how to manage the lance, an art which was taught by making him ride a career against a wooden figure holding a buckler, called a quintaine. This quintaine turned on an axis; and as there was a wooden sword in the other hand of the supposed opponent, the young cavalier, if he did not manage his horse and weapon with address, was liable to receive a blow when the shock of his charge made the quintaine spin round.

Besides these exercises, the noble youth was required to do the work which, in some respects, belonged to a menial, but not as a menial. He attended his lord during the chase, the rules of which, as an image of war, and as held the principal occupation of a gentleman during peace, were carefully inculcated. He was taught the principal blasts or notes of *venerie*, to be sounded when the hounds were uncoupled, when the prey was on foot, when he was brought to bay, and when he fell. This art did not tend solely to amusement. The "gentle damosel," to use the language of the times, learned to bear the fatigue, the hunger and thirst, which huntsmen are exposed to. By the necessity of encountering and dispatching a stag, a boar, or a wolf, at bay, he learned promptitude and courage in the use of his weapons. The accuracy with which he was required to study the attacks of the hunted animal's course gave him habits of attention and reflection. In the days and nights spent in the chase, amid wide and pathless forests, he acquired the art, so necessary to a soldier, of remarking and studying the face of the country. When benighted, he was taught to steer his course by the stars, if they were visible; if not, to make his couch with patience on the withered leaves, or in a tree. Had he lost his way by day-time, he distinguished the points of the compass by remarking which side of the trees were most covered with moss, and from which they threw their branches most freely; circumstances which, compared with the known course of the prevailing wind, afforded him the necessary information.

The ceremonial of the chase was to be acquired, as well as its arts. To brittle or break the deer (in French *faire la curée*), in plain terms, to flay and disembowel the stag, a matter in which much precision was required, and the rules of which were ascribed to the celebrated Sir Tristram of Lionesse, was an indispensable requisite of the page's education. Nor did his concern with the venison end here; he placed it on the table, waited during the banquet, and carved the ponderous dishes when required or permitted to do so. Much grace and delicacy, it was supposed, might be displayed on these occasions; and in one romance we read of the high birth and breeding of a page being ascertained, by his scrupulously declining to use a towel to wipe his hands, when washed, before he began to carve, and contenting himself with waving them in the air till they dried of themselves. It is perhaps difficult to estimate the force of this delicacy, unless by supposing that he had not a towel or napkin appropriated to his own separate use.

Chivalry.

Amidst these various instructions the page was often required to wait upon the ladies, rather as attending a sort of superior beings, to whom adoration and obsequious service were due, than as ministering to the convenience of human creatures like himself. The most modest demeanour, the most profound respect, was to be observed in the presence of these fair idols. Thus the veneration due to the female character was taught to the acolyte of chivalry, by his being placed so near female beauty, yet prohibited the familiarity which might discover female weakness. Love frequently mingled with this early devotion, and the connection betwixt some lady of distinction and her gallant knight is often, in romantic fiction, supposed to have originated from some early affection. In a romance called *The Golden Thread* (of which we have only seen a modern edition in German, but which has many features of originality), when the daughter of the count bestows her annual gifts on her father's household, she gives the page Leofried, in derision, a single thread of gold tissue. To show the value which he places upon the most minute memorial, coming from such a hand, the youth opens a wound in his bosom, and deposits the precious thread in the neighbourhood of his heart. The Dame des Belles Cousines, whom we have already mentioned, was assuredly not the only lady of high rank who was tempted to give a handsome young page the benefit of her experience in completing his education. This led the way to abuse; and the custom of breeding up youths as pages in the houses of the great, although it survived the decay of chivalry, was often rather the introduction to indolence, mischief, and debauchery, than to useful knowledge and the practice of arms. The proper purposes of this preliminary part of chivalrous education are well given by one of the characters in Ben Jonson's *New Inn;* and he is answered by another, who alleges, with satire resembling that of Juvenal, the modern corruptions of the order of pages. Lord Lovel has requested mine host to give him his son for a page. The host answers, by declaring he would rather hang his child with his own hand

> Than damn him to that desperate course of life.
> *Lovel.* Call you that desperate which, by a line
> Of institution from our ancestors,
> Hath been derived down to us, and received
> In a succession, for the noblest way
> Of breeding up our youth in letters, arms,
> Fair mein, discourses, civil exercises,
> And all the blazon of a gentleman?
> Where can he learn to vault, to ride, to fence,
> To mar his body gracefully, to speak
> His language purer, or to turn his mind
> Or manners more to the harmony of nature,
> Than in those nurseries of nobility?
> *Host.* Aye, that was when the nursery's self was noble,
> And only virtue made it not the market.

And he replies by enumerating instances of the decay of honour among the nobles, and of the debauchery of their household pages. In La Noue's *Political and Military Discourses* is a similar complaint of the hazards to which the morals of young gentlemen were exposed while acting in this domestic capacity. Nevertheless the custom of having young gentlemen thus bred, continued in a certain degree down to the last century, although those destined to such employments became by degrees of a lower quality. In some few instances the institution was maintained in its purity; and the page, when leaving the family in which he was educated, usually obtained a commission. The last instance we know was that of a gentleman bred a page in the family of the Duchess of Buccleuch and Monmouth, who died, during the reign of George III. a general officer in his majesty's service.

Chivalry.

The squire.

When advancing age and experience in the use of arms had qualified the page for the hardships and dangers of actual war, he was removed from the lowest to the second gradation of chivalry, and became an *Escuyer*, Esquire, or SQUIRE. The derivation of this phrase has been much contested. It has been generally supposed to be derived from its becoming the official duty of the esquire to carry the shield (*escu*) of the knight his master, until he was about to engage the enemy. Others have fetched the epithet (more remotely certainly) from *scuria*, a stable, the charger of the knight being under the especial care of the squire. Others again ascribe the derivation of the word to the right which the squire himself had to carry a shield, and to blazon it with armorial bearings. This, in later times, became almost the exclusive meaning attached to the appellative esquire; and, accordingly, if the phrase now means anything, it means a gentleman having right to carry arms. There is reason, however, to think that this is a secondary meaning of the word, for we do not find the word escuyer applied as a title of rank, until so late as the Ordonnance of Blois, in 1579.

The candidate for the honours of chivalry, now an immediate attendant on the knight or nobleman, was withdrawn from the private apartments of the ladies, and only saw them upon occasions of stated ceremony. In great establishments there were squires of different ranks, and destined for different services; but we shall confine ourselves to those general duties which properly belonged to the office. The squire assisted his master in the offices at once of a modern valet de chambre and groom—he attended to dress and to undress him, trained his horses to the menage, and kept his arms bright and burnished. He did the honours of the household to the strangers who visited it; and the reputation of the prince or great lord whom he served was much exalted by the manner in which these courteous offices were discharged. In the words of Chaucer, describing the character of the squire,

> Curteis he was, lowly and servisable,
> And carf before his fader at the table.

The squire was also expected to perfect himself in the accomplishments of the period, and not only to be a master of the ceremonial of the feast, but to be capable of enlivening it by his powers of conversation. He was expected to understand chess, draughts, and other domestic games. Poetry and music, if he had any turn for these beautiful arts, and whatever other accomplishments could improve the mind or the person, were accounted to grace his station. And accordingly Chaucer's squire, besides that he was "singing or fluting all the day,"

> —Could songs make, and well indite,
> Just, and eke dance, and well pourtray and write.

Unquestionably few possessed all these attributes; but the poet, with his usual precision and vivacity, has given us the picture of a perfect esquire.

To understand the squires' mode of life more particularly, it is necessary to consider that which was led in the courts and castles of the middle ages. Froissart has given us a very striking account of the mode of house-keeping in the family of Gaston, earl of Foix, a prince whose court was considered as a first-rate nursery for the noble youth; and, from his lively description, we may in some measure conceive the mode in which the esquires spent their time. Froissart abode in his house above twelve weeks, much recommended to the favourable notice of the earl, by his having brought with him a book containing all the songs, ballads, and virilays, which Wencislaus of Bohemia, the gentle Duke of Brabant, had made, and the historian himself had compiled or transcribed. "Every night after supper," says Froissart, "I read thereon to him, and while I read there was none durst speak any thing to interrupt me, so much did the earl delight in listening." The quotation necessary to describe the Earl of Foix, and the economy of his household, must necessarily be a long one, but it is a picture by the hand of an inimitable artist, of a school of chivalry when chivalry was at its highest pitch, and we are unwilling to destroy the likeness by abridging it.

Chivalry.

"This erle Gascone of Foix, with whom I was, at that tyme, he was of a fyftie yere of age and nyne: and, I say, I have in my tyme sene many knights, kynges, princes, and others, but I neuer saw none like him of personage, nor of so fayre forme, nor so well made, his vysage fayre, sanguyne, and smylyng, his eyen gray and amorous, wher as he lyst to set his regarde; in euery thyng he was so parfite that he can not be praised to moche; he loued that ought to be beloued, and hated that ought to be hated: he was a wyse knyght, of highe enterprise, and of good counsayle; he neuer had myscreant with hym; he sayd many orisons every day, a nocturn of the psalter, matyns of our Lady, of the Holy Goost, and of the crosse, and dirigè euery day; he gaue fyue florins, in small monies, at his gate to poor folkes for the loue of God; he was large and courtesse in gyftes; he could ryght well take where it parteyned to hym, and to delyuer agayne wher as he ought; he loued hoũdes of all beestes, wynter and somer he loued huntyng; he neuer loued folly, outrage, nor foly larges; euery moneth he wolde knowe what he spended; he tooke in his countre to receyue his reuenwes, and to serue him, notable persóns, that is to saye, xii. récyuours, and euer fro 11. monethes to two monethes, two of them shulde serue for his receyte; for, at the two monethes end, he wolde change and put other two into that offiyce; and one that he trusted best shulde be his comptroller, and to hym all other shulde accompt, and the comptroller shulde accõpt to hym by rolles and bokes written, and the comptes to remayne still with therle: he had certeyne cofers in his chambre, out of the whiche oftetymes he wolde take money to gyve to lordes, knightes, and squyers, suche as came to hym, for none shulde departe from him without some gift, and yet dayly he multiplyed his treasure, to resyst the aduẽtures and fortunes that he douted; he was of good and easy acquayntance with every man, and amorously wolde speke to thẽ; he was short in counsayle, and answers; he had four secretaries, and at his rising they must ever be redy at his hande, without any callynge; and whan any letter were delyuered him, and that he had reed it, than he wolde calle them to write agayne, or els for some other thynge. In this estate therle of Foix liued. And at mydnight, whan he came out of his chambre into the hall to supper, he had ever before him xii. torches brennyng, borne by xii. varlettes standying before his table all supper; they gaue a gret light, and the hall ever full of knightes and squyers, and many other tables dressed to suppe who wolde; ther was none should speke to hym at his table, but if he were called; his meate was lightlye wylde foule, the legges and wynges alonely, and in the day he dyd but lytell eate and drĩke; he had great pleasure in armony of instrumẽtes; he coude do it right well hymselfe, he wolde have songes song before him, he wolde gladlye se conseytes and fantesies at his table. And or I came to his court, I had been in many courtes of kynges, dukes, princes, erles, and great ladyes, but I was neuer in none y so well liked me, nor ther was none more reioysed in dedes of armes, than the erle dyde: there was sene in his hall, chãbre and court, knightes and squyers of honour goyng up and downe, and talking of armes and amours; all honour ther was found, all maner of tidynges of every realme and countre ther might be herde, for out

of every coūtre there was resort for the valyantnesse of this erle."[1]

While the courage of the young aspirant to the honours of knighthood was animated, and his emulation excited, by the society in which he was placed, and the conversation to which he listened,—while everything was done which the times admitted to refine his manners, and, in a certain degree, to cultivate his understanding,—the personal exercises to which he had been trained while a page were now to be pursued with increasing assiduity, proportional to the increase of his strength. "He was taught," says a historian, speaking of Bouçicaut, while a squire, "to spring upon a horse, while armed at all points; to exercise himself in running; to strike for a length of time with the axe or club; to dance and throw somersets, entirely armed, excepting the helmet; to mount on horseback behind one of his comrades, by barely laying his hands on his sleeve; to raise himself betwixt two partition walls to any height, by placing his back against the one, and his knees and hands against the other; to mount a ladder, placed against a tower, upon the reverse or under side, solely by the aid of his hands, and without touching the rounds with his feet; to throw the javelin, to pitch the bar;" to do all, in short, which could exercise the body to feats of strength and agility, in order to qualify him for the exploits of war. For this purpose also, the esquires had their tourneys separate and distinct from those of the knights. They were usually solemnized on the eve of the more formal and splendid tournaments, in which the knights themselves displayed their valour; and lighter weapons than those of the knights, though of the same kind, were employed by the esquires. But, as we shall presently notice, the most distinguished among the esquires were (notwithstanding the high authority of the knight of La Mancha to the contrary) frequently admitted to the honours and dangers of the more solemn encounter.

In actual war the page was not expected to render much service, but that of the squire was important and indispensable. Upon a march, he bore the helmet and shield of the knight, and led his horse of battle, a tall heavy animal, fit to bear the weight of a man in armour, but which was led in hand upon a march, while the knight rode an ambling hackney. The squire was also qualified to perform the part of an armourer, not only lacing his master's helmet and buckling his cuirass, but also closing with a hammer the rivets by which the various pieces were united to each other. This was a point of the utmost consequence; and many instances occur of mischances happening to celebrated warriors when the duty was negligently performed. In the actual shock of battle the esquire attended closely on the banner of his master, or on his person, if he were only a knight bachelor, kept pace with him during the melée, and was at hand to remount him when his steed was slain, or relieve him when oppressed by numbers. If the knight made prisoners, they were the charge of the esquire; if the esquire himself fortuned to make one, the ransom belonged to his master.

On the other hand, the knights who received these important services from their esquires were expected to display towards them that courteous liberality which made so distinguished a point of the chivalrous character. Lord Audley led the van of the Black Prince's army at the battle of Poitiers, attended by four squires, who had promised not to fail him. They distinguished themselves in the front of that bloody day, leaving such as they overcame to be made prisoners by others, and ever pressing forwards where resistance was offered. Thus they fought in the chief of the battle, until Lord James Audley was sorely wounded, and his breath failed him. At the last, when the battle was gained, the four faithful esquires bore him out of the press, disarmed him, and staunched and dressed his wounds as they could. As the Black Prince called for the man to whom the victory was in some measure owing, Lord Audley was borne before him in a litter, when the prince, after having awarded to him the praise and renown above all others who fought on that day, bestowed on him five hundred marks of yearly revenue, to be assigned out of his heritage in England. Lord Audley accepted of the gift with due demonstration of gratitude; but no sooner was he brought to his lodging, than he called before him the four esquires by whom he had been so gallantly seconded, and the nobles of his lineage, and informed his kinsmen, "Sirs, it has pleased my lord the prince to bestow on me five hundred marks of heritage, of which I am unworthy; for I have done him but small service. Behold, Sirs, these four squires, which have always served me truly, and specially this day; the honour that I have is by their valour. Therefore, I resign to them and their heirs for ever, in like manner as it was given to me, the noble gift which the prince hath assigned me." The lords beheld each other, and agreed it was a proof of great chivalry to bestow so royal a gift, and gladly undertook to bear witness to the transfer. When Edward heard these tidings, he sent for Lord Audley, and desired to know why he had bestowed on others the gift he had assigned him, and whether it had not been acceptable to him: "Sir," said Lord Audley, "these four squires have followed me well and truly in several severe actions, and at this battle they served me so well, that had they done nothing else, I had been bound to reward them. I am myself but a single man; but, by aid of their united strength and valour, I was enabled to execute the vow which I had made to give the onset in the first battle in which the king of England or his sons should be present; and had it not been for them, I must have been left dead on the field. This is the reason I have transferred your highnesses bounty, as to those by whom it was best deserved." The Black Prince not only approved of and confirmed Lord Audley's grant, but conferred upon him, not to be outdone in generosity, a yearly revenue of six hundred marks more, for his own use.[2] The names of the esquires who thus distinguished themselves, and experienced such liberality at the hands of their leader, were Delves of Doddington, Dutton of Dutton, Fowlishurst of Crewe, and Hawkestone of Wreynehill, all Cheshire families. This memorable instance may suffice to show the extent of gratitude which the knights entertained for the faithful service of their squires; but it also leads us to consider some other circumstances relating to the order of esquire.

Although, in its primitive and proper sense, the state of esquire was merely preparatory to that of knighthood, yet it is certain that many men of birth and property rested content with attaining that first step, and, though greatly distinguished by their feats of arms, never rose, nor apparently sought to rise, above the rank which it conferred. It does not appear that any of the esquires of Lord Audley were knighted after the battle of Poitiers, although there can be no doubt that their rank, as well as their exploits, entitled them to expect that honour. The truth seems to be, that it may frequently have been more convenient, and scarcely less honourable, to remain in the unenvied and unpretending rank of esquire, than to aspire to that of knighthood, without a considerable fortune to supply the expenses of that dignity. No doubt, in theory,

[1] Froissart's *Chronicles*, translated by Lord Berners.

[2] Froissart. Barne's *History of Edward III.*

the simplest knight-bachelor was a companion, and in some degree equal with princes. But, in truth, we shall presently see, that, where unsupported by some sort of income to procure suitable equipment and retainers, that dignity was sometimes exposed to ridicule. Many gallant gentlemen, therefore, remained esquires, either attached to the service of some prince or eminent nobleman, or frequently in a state of absolute independence, bringing their own vassals to the field, whom, in such cases, they were entitled to muster under a *penoncele*, or small triangular streamer, somewhat like the naval pendant of the present day. The reader of history is not, therefore, to suppose, that where he meets with an esquire of distinguished name, he is therefore necessarily to consider him as a youthful candidate for the honour of knighthood, and attending upon some knight or noble. This is, indeed, the primitive, but not the uniform meaning of the title. So many men of rank and gallantry appear to have remained esquires, that, by degrees, many of the leading distinctions between them and the knights were relaxed or abandoned. In Froissart's *Chronicles* we find that esquires frequently led independent bodies of men, and, as we have before hinted, mingled with the knights in the games of chivalry; the difference chiefly consisting in title, precedence, the shape of the flag under which they arrayed their followers, and the fashion of their armour. The esquires were permitted to bear a shield, emblazoned, as we have already seen, with armorial bearings. There seems to have been some difference in the shape of the helmet; and the French esquire was not permitted to wear the complete hauberk, but only the shirt of mail, without hood or sleeves. But the principal distinction between the independent esquire (terming him such who was attached to no knight's service) and the knight, was the spurs, which the esquire might wear of silver, but by no means gilded.

To return to the esquires most properly so termed, their dress was, during their period of probation, simple and modest, and ought regularly to have been made of brown, or some other uniform and simple colour. This was not, however, essential. The garment of Chaucer's squire was embroidered like a meadow. The petit Jehan de Saintré was supplied with money by his mistress to purchase a silken doublet and embroidered hose. There is also a very diverting account, in the *Memoirs of Bertrand de Guesclin*, of the manner in which he prevailed on his uncle, a covetous old churchman, to assign him money for his equipment on some occasion of splendour. We may therefore hold, that the sumptuary laws of squirehood were not particularly attended to, or strictly enforced.

A youth usually ceased to be a page at fourteen, or a little earlier, and could not regularly receive the honour of knighthood until he was one and twenty. But if their distinguished valour anticipated their years, the period of probation was shortened. Princes of the blood-royal, also, and other persons of very high eminence, had this term abridged, and sometimes so much so as to throw a ridicule upon the order of knighthood, by admitting within "the temple of honour," as it was the fashion of the times to call it, children who could neither understand nor discharge the duties of the office to which they were thus prematurely called.

Knights. The third and highest rank of chivalry was that of knighthood. In considering this last dignity, we shall first inquire how it was conferred; secondly, the general privileges and duties of the order; thirdly, the peculiar ranks into which it was finally divided, and the difference betwixt them.

The investiture. Knighthood was, in its origin, an order of a republican, or at least an oligarchic nature; arising, as has been shown, from the customs of the free tribes of Germany, and, in its essence, not requiring the sanction of a monarch. On the contrary, each knight could confer the order of knighthood upon whomsoever preparatory noviciate and probation had fitted to receive it. The highest potentate sought the *accolade*, or stroke which conferred the honour, at the hands of the worthiest knight whose achievements had dignified the period. Thus Francis I. requested the celebrated Bayard, *the Good Knight without reproach or fear*, to make him; an honour which Bayard valued so highly, that, on sheathing his sword, he vowed never more to use that blade, except against Turks, Moors, and Saracens. The same principle was carried to extravagance in a romance, where the hero is knighted by the hand of Sir Lancelot of the Lake, when dead. A sword was put into the hand of the skeleton, which was so guided as to let it drop on the neck of the aspirant. In the time of Francis I. it had already become customary to desire this honour at the hands of greatness rather than valour, so that the king's request was considered as an appeal to the first principles of chivalry. In theory, however, the power of creating knights was supposed to be inherent in every one who had reached that dignity. But it was natural that the soldier should desire to receive the highest military honour from the general under whose eye he was to combat, or from the prince or noble at whose court he passed as page and squire through the gradations of his noviciate. It was equally desirable, on the other hand, that the prince or noble should desire to be the immediate source of a privilege so important. And thus, though no positive regulation took place on the subject, ambition on the part of the aspirant, and pride and policy on that of the sovereign princes and nobles of high rank, gradually limited to the latter the power of conferring knighthood, or drew at least an unfavourable distinction between the knights dubbed by private individuals, and those who, with more state and solemnity, received the honoured title at the hand of one of high rank. Indeed, the change which took place respecting the character and consequences of the ceremony, naturally led to a limitation in the right of conferring it. While the order of knighthood merely implied a right to wear arms of a certain description, and to bear a certain title, there could be little harm in intrusting, to any one who had already received the honour, the power of conferring it on others. But when this highest order of chivalry conferred not only personal dignity, but the right of assembling under the banner, or pennon, a certain number of soldiers,—when knighthood implied not merely personal privileges, but military rank,—it was natural that sovereigns should use every effort to concentrate the right of conferring such distinction in themselves, or their immediate delegates. And latterly it was held, that the rank of knight only conferred those privileges on such as were dubbed by sovereign princes.

The times and place usually chosen for the creation of knights were favourable to the claim of the sovereigns to be the proper fountain of chivalry. Knights were usually made either on the eve of battle, or when the victory had been obtained; or they were created during the pomp of some solemn warning or grand festival. In the former case, the right of creation was naturally referred to the general or prince who led the host; and in the latter, to the sovereign of the court where the festival was held. The forms in these cases were very different.

When knights were made in the actual field of battle, little solemnity was observed, and the form was probably the same with which private individuals had, in earlier times, conferred the honour on each other. The novice, armed at all points, but without helmet, sword, and spurs, came before the prince or general at whose hands he was to receive knighthood, and kneeled down, while two per-

Chivalry. sons of distinction, who acted as his godfathers, and were supposed to become pledges for his being worthy of the honour to which he aspired, buckled on his gilded spurs, and belted him with his sword. He then received the accolade, a slight blow on the neck, with the flat of the sword, from the person who dubbed him, who, at the same time, pronounced a formula to this effect; "I dub thee knight, in the name of God and St Michael (or in the name of the Father, Son, and Holy Ghost). Be faithful, bold, and fortunate." The new-made knight had then only to take his place in the ranks of war, and endeavour to distinguish himself by his forward gallantry in the approaching action, when he was said to win his spurs. It is well known that, at the battle of Cressy, Edward III. refused to send succours to the Black Prince, until he should hear that he was wounded or dismounted, being determined he should, on that memorable day, have full opportunity to *win his spurs*. It may be easily imagined, that on such occasions the courage of the young knights was wound up to the highest pitch; and, as many were usually made at the same time, their gallantry could not fail to have influence on the fortune of the day. At the siege of Tholouse (1159), Henry II. of England made thirty knights at once, one of whom was Malcolm IV. king of Scotland. Even on these occasions the power of making knights was not understood to be limited to the commander-in-chief. At the fatal battle of Homildown, in 1401, Sir John Swinton, a warrior of distinguished talents, observing the slaughter made by the English archery, exhorted the Scots to rush on to a closer engagement. Adam Gordon, between whose family and that of Swinton a deadly feud existed, hearing this sage counsel, knelt down before Swinton, and prayed him to confer on him the honour of knighthood, which he desired to receive from the wisest and boldest knight in the host. Swinton conferred the order; and they both rushed down upon the English host, followed only by a few cavalry. If they had been supported, the attack might have turned the fate of the day. But none followed their gallant example, and both champions fell. It need hardly be added, that the commander, whether a sovereign prince or not, equally exercised the privilege of conferring knighthood. In the old ballad of the battle of Otterburn, Douglas boasts that, since he had entered England, he had

With brand dubb'd many a knight.

But it was not in camps and armies alone that the honours of knighthood were conferred. At the *Cour Plenière*, a high court to which sovereigns summoned their crown vassals at the solemn festivals of the church, at the various occasions of solemnity which occurred in the royal family, from marriage, birth, baptism, and the like, the monarch was wont to confer on novices in chivalry its highest honour, and the ceremonies used on such investiture added to the dignity of the occasion. It was then that the full ritual was observed which, on the eve of battle, was necessarily abridged or omitted. The candidates watched their arms all night in a church or chapel, and prepared for the honour to be conferred on them, by vigil, fast, and prayer. They were solemnly divested of the brown frock, which was the appropriate dress of the squire; and having been bathed, as a symbol of purification of heart, they were attired in the richer garb appropriate to knighthood. They were then solemnly invested with the appropriate arms of a knight; and it was not unusual to call the attention of the novice to a mystical or allegorical explanation of each piece of armour as it was put on. These exhortations consisted in strange and extravagant parallels betwixt the temporal and spiritual state of warfare, in which the metaphor was hunted down in every possible shape. The under dress of the knight was a close jacket of chamois leather, over which was put the mail shirt, composed of rings of steel artificially fitted into each other, as is still the fashion in some parts of Asia. A suit of plate armour was put on over the mail shirt, and the legs and arms were defended in the same manner. Even this accumulation of defensive armour was by some thought insufficient. In the combat of the Infantes of Carrion with the champions of the Cid, one of the former was yet more completely defended, and to little purpose.

Onward into Ferrand's breast the lance's point is driven
Full upon his breastplate, nothing would avail;
Two breastplates Ferrand wore, and a coat of mail,
The two are riven in sunder, the third stood him in stead,
The mail sunk in his breast, the mail and the spear head;
The blood burst from his mouth, that all men thought him dead.[1]

The novice being accoutred in his knightly armour, but without helmet, sword, and spurs, a rich mantle was flung over him, and he was conducted in solemn procession to the church or chapel in which the ceremony was to be performed, supported by his godfathers, and attended with as much pomp as circumstances admitted. High mass was then said, and the novice, advancing to the altar, received from the sovereign the accolade. The churchman present, of highest dignity, often belted on his sword, which, for that purpose, had been previously deposited on the altar; and the spurs were sometimes fastened on by ladies of quality. The oath of chivalry was then taken, to be loyal to God, the king, and the ladies. Such were the outlines of the ceremony, which, however, was varied according to circumstances. A king of Portugal knighted his son in presence of the dead body of the Marquis of Marialva, slain in that day's action, and impressively conjured the young prince to do his duty in life and death, like the good knight who lay dead before him. Alms to the poor, largesses to the heralds and minstrels, a liberal gift to the church, were necessary accompaniments to the investiture of a person of rank. The new-made knight was conducted from the church with music and acclamations, and usually mounted his horse and executed some curvets in presence of the multitude, couching his lance, and brandishing it as if impatient to open his knightly career. It was at such times also that the most splendid tournaments were executed, it being expected that the young knights would display the utmost efforts to distinguish themselves. Such being the solemnities with which knighthood was conferred, it was no wonder that the power of conferring it should, in peace as well as in war, be almost confined to sovereign princes, or nobles who nearly equalled them in rank and independence. By degrees these restrictions were drawn more and more close, and at length it was held that none but a sovereign, or a commander-in-chief displaying the royal banner, and vested with plenary and vice-regal authority, could confer the degree of knighthood. Queen Elizabeth was particularly jealous of this part of her prerogative; and nothing more excited her displeasure and indignation against her favourite Essex, than the profuseness with which he distributed the honour at Cadiz, and afterwards in Ireland. These anecdotes, however, belong to the decay of chivalry.

Arms and privileges of a knight.

The knight had several privileges of dignity and importance. He was associated into a rank wherein kings and princes were in one sense only his equals. He took precedence in war and in counsel, and was addressed by

[1] See Translations from the Spanish Metrical Romance on the subject of the Cid, appended to Mr Southey's *Cid*.

Chivalry. the respectful title of *Messire* in French, and *Sir* in English, and his wife by that of Madame and Dame. A knight was also, in point of military rank, qualified to command any body of men under a thousand. His own service was performed on horseback, and in complete armour of many various fashions, according to the taste of the warriors and the fashion of the age. Chaucer has enumerated some of these varieties.

With him ther wenten knights many on.
Som wol ben armed in an habergeon,
And in a brest plate, and in a gipon;
And som wol have a pair of plates large;
And som wol have a pruse sheld, or a targe;
Some wol ben armed on his legges wele,
And have an axe, and some a mace of stele.
Ther n'is no newe guise, that it n'as old.
Armed they weren, as I have you told,
Everich after his opinion.

The weapons of offence, however, most appropriate to knighthood were the lance and sword. They had frequently a battle-axe or mace at their saddle-bow, a formidable weapon even to men sheathed in iron like themselves. The knight had also a dagger, which he used when at close quarters. It was called the dagger of mercy, probably because, when unsheathed, it behoved the antagonist to crave mercy or to die. The management of the lance and of the horse was the principal requisite of knighthood. To strike the foeman either on the helmet or full upon the breast with the point of the lance, and at full speed, was accounted perfect practice; to miss him, or to break a lance across, *i. e.* athwart the body of the antagonist, without striking him with the point, was accounted an awkward failure; to strike his horse, or to hurt his person under the girdle, was conceived a foul or felon action, and could only be excused by the hurry of a general encounter. When the knights, from the nature of the ground, or other circumstances, alighted to fight on foot, they used to cut some part from the length of their spears, in order to render them more manageable, like the pikes used by infantry. But their most formidable onset was when mounted and "in host." They seem then to have formed squadrons not unlike the present disposition of cavalry in the field,—their squires forming the rear rank, and performing the part of serrefiles. As the horses were trained in the tourneys and exercises to run upon each other without flinching, the shock of two such bodies of heavy-armed cavalry was dreadful, and the event usually decided the battle; for, until the Swiss showed the superior steadiness which could be exhibited by infantry, all great actions were decided by the men-at-arms. The yeomanry of England, indeed, formed a singular exception; and, from the dexterous use of the long bow, to which they were trained from infancy, were capable of withstanding and destroying the mail-clad chivalry both of France and Scotland. Their shafts, according to the exaggerating eloquence of a monkish historian, Thomas of Walsingham, penetrated steel coats from side to side, transfixed helmets, and even splintered lances and pierced through swords! But against every other pedestrian adversary, the knights, squires, and men-at-arms had the most decided advantage, from their impenetrable armour, the strength of their horses, and the fury of their onset. To render success yet more certain, and attack less hazardous, the horse, on the safety of which the rider so much depended, was armed *en barbe*, as it was called, like himself. A masque made of iron covered the animal's face and ears; it had a breastplate, and armour for the croupe. The strongest horses were selected for this service; they were generally stallions, and to ride a mare was reckoned base and unknightly.

To distinguish him in battle, as his face was hid by the helmet, the knight wore above his armour a surcoat, as it was called, like a herald's coat, on which his arms were emblazoned. Others had them painted on the shield, a small triangular buckler of light wood, covered with leather, and sometimes plated with steel, which, as best suited him, the knight could either wield on his left arm, or suffer to hang down from his neck, as an additional defence to his breast, when the left hand was required for the management of the horse. The shape of these shields is preserved, being that on which heraldric coats are most frequently blazoned. But it is something remarkable, that no one of those *heater*[1] shields has been preserved in the Tower, or, so far as we know, in any English collection. The helmet was surmounted by a crest, which the knight adopted after his own fancy. There was deadly offence taken if one knight, without right, assumed the armorial bearings of another; and history is full of disputes on that head, some of which terminated fatally. The heralds were the persons appealed to on these occasions, when the dispute was carried on in peace; and hence flowed the science, as it was called, of heraldry, with all its fantastic niceties. By degrees the crest and device became also hereditary, as well as the bearings on the shield. In addition to his armorial bearings, the knight distinguished himself in battle by shouting out his war-cry, which was echoed by his followers. It was usually the name of some favourite saint, united with that of his own family. If the knight had followers under his command, they re-echoed his war-cry, and rallied round his pennon or flag at the sound. The pennon differed from the penoncel, or triangular streamer which the squire was entitled to display, being double the breadth, and indented at the end like the tail of a swallow. It presented the appearance of two penoncels united at the end next the staff, a consideration which was not perhaps out of view in determining its shape. Of course, the reader will understand that those knights only displayed a pennon who had retainers to support and defend it, the mounting this ensign being a matter of privilege, not of obligation.

Froissart's heart never fails to overflow when he describes the encounter of a body of men-at-arms, arrayed in the manner we have described; he dwells with enthusiasm on the leading circumstances. The waving of banners and pennons, the dashing of spurs into the sides of chargers, and their springing forward to battle; the glittering of armour, the glancing of plumes, the headlong shock and splintering of the lances, the swords flashing through the dust over the heads of the combatants, the thunder of the horses' feet and the clash of armour, mingled with the war-cry of the combatants and the groans of the dying, form the mingled scene of tumult, strife, and death, which the canon has so frequently transferred to his chivalrous pages.

It was not in war alone that the adventurous knight was to acquire fame. It was his duty, as we have seen, to seek adventures throughout the world, whereby to exalt his own fame and the beauty of his mistress, which inspired such deeds. In our remarks upon the general spirit of the institution, we have already noticed the frantic enterprises which were seriously undertaken and punctually executed by knights desirous of a name. On these occasions, the undertaker of so rash an enterprise often owed his life to the sympathy of his foes, who had great respect for any one engaged in the discharge of a vow of

[1] So called because resembling in shape the heater of a smoothing-iron.

chivalry. When Sir Robert Knowles passed near Paris, at the head of an English army, in the reign of Edward III. the following remarkable incident took place:

"Now it happened, one Tuesday morning, when the English began to decamp, and had set fire to all the villages wherein they were lodged, so that the fires were distinctly seen from Paris, a knight of their army, who had made a vow the preceding day, that he would advance as far as the barriers and strike them with his lance, did not break his oath, but set off with his lance in his hand, his target on his neck, and completely armed except his helmet, and, spurring his steed, was followed by his squire on another courser, carrying the helmet. When he approached Paris, he put on the helmet, which his squire laced behind. He then galloped away, sticking spurs into his horse, and advanced prancing to strike the barriers. They were then open, and the lords and barons within imagined he intended to enter the town; but he did not so mean, for having struck the gates according to his vow, he checked his horse and turned about. The French knights who saw him thus retreat, cried out to him, 'Get away! get away! thou hast well acquitted thyself.' As for the name of this knight I am ignorant of it, nor do I know from what country he came; but he bore for his arms gules à deux fousses noir, with une bordure noir non endentée.

"However, an adventure befel him, from which he had not so fortunate an escape. On his return he met a butcher on the pavement in the suburbs, a very strong man, who had noticed him as he had passed him, and who had in his hand a very sharp and heavy hatchet with a long handle. As the knight was returning alone, and in a careless manner, the valiant butcher came on one side of him, and gave him such a blow between the shoulders, that he fell on his horse's neck: he recovered himself, but the butcher repeated the blow on his head, so that the axe entered it. The knight, through excess of pain, fell to the earth, and the horse galloped away to the squire, who was waiting for his master in the fields at the extremity of the suburbs. The squire caught the courser, but wondered what was become of his master; for he had seen him gallop to the barriers, strike them, and then turn about to come back. He therefore set out to look for him; but he had not gone many paces before he saw him in the hands of four fellows, who were beating him as if they were hammering on an anvil. This so much frightened the squire, that he dared not advance further, for he saw he could not give him any effectual assistance: he therefore returned as speedily as he could.

"Thus was this knight slain; and those lords who were posted at the barriers had him buried in holy ground. The squire returned to the army, and related the misfortune which had befallen his master. All his brother warriors were greatly displeased thereat." (Johnes's *Froissart*, vol. ii. p. 63.)

An equally singular undertaking was that of Galeazzo of Mantua, as rehearsed by the venerable Doctor Paris de Puteo, in his treatise *De Duello et Re Militari*, and by Brantome in his *Essay on Duels.* Queen Joan of Naples, at a magnificent feast given in her castle of Gaeta, had given her hand to Galeazzo for the purpose of opening the ball. The dance being finished, the gallant knight kneeled down before his royal partner, and, in order to make fitting acknowledgment of the high honour done him, took a solemn vow to wander through the world wherever deeds of arms should be exercised, and not to rest until he had subdued two valiant knights, and had presented them prisoners at her royal footstool, to be disposed of at her pleasure. Accordingly, after a year spent in visiting various scenes of action in Brittany, England, France, Burgundy, and elsewhere, he returned like a falcon with his prey in his clutch, and presented two prisoners of knightly rank to Queen Joan. The queen received the gift very graciously; and, declining to avail herself of the right she had to impose rigorous conditions on the captives, she gave them liberty without ransom, and bestowed on them, over and above, several marks of liberality. For this she is highly extolled by Brantome and Dr Paris, who take the opportunity of censuring the very opposite conduct of the canons of St Peter's Church at Rome, upon whom a certain knight had bestowed a prisoner taken in single combat. These ungracious churchmen received the gift as if it had been that of a wild beast for a menagerie, permitting the poor captive the freedom of the church indeed, but prohibiting him to go one step beyond the gate. In which condition, worse than death, they detained the vanquished knight for some time, and were justly blamed, as neither understanding Christian charity nor gentleman-like courtesy.

We return to consider the duties of a knight. His natural and proper element was war; but in time of peace, when there was no scope for the fiery spirit of chivalry, the knights attended the tourneys proclaimed by different princes, or, if these amusements did not occur, they themselves undertook feats of arms, to which they challenged all competitors. The nature of these challenges will be best understood from an abridged account of the *pas d'armes*, called the *Justs* of Saint Inglebert, or Sandyng Fields. This emprize was sustained by three gallant knights of France, Bouçicaut, Reynold de Roy, and Saint Py or Saimpi. Their articles bound them to abide thirty days at Saint Inglebert, in the marches of Calais, there to undertake the encounter of all knights and squires, Frenchmen, or strangers who should come hither, for the breaking of five spears, sharp, or with rockets, at their pleasure. On their lodgings they hung two shields called of peace and war, with their armorial blazons on each. The stranger desiring to just was invited to come or send, and touch which shield he would. The weapons of courtesy were to be employed if he chose the shield of peace, if that of war, the defenders were to give him the desired encounter with sharp weapons. The stranger knights were invited to bring some nobleman with them, to assist in judging the field; and the proclamation concludes with an entreaty to knights and squires strangers, that they will not hold this offer as made for any pride, hatred, or ill-will, but only that the challengers do it to have their honourable company and acquaintance, which with their whole heart they desire. They were assured of a fair field, without fraud or advantage; and it was provided that the shields used should not be covered with iron or steel. The French king was highly joyful of this gallant challenge (although some of his council doubted the wisdom of permitting it to go forth), and exhorted the challengers to regard the honour of their prince and realm, and spare no cost at the solemnity, for which he was willing to contribute ten thousand francs. A number of knights and squires came from England to Calais to accept this gallant invitation; and at the entrance of the "fresh and joly month of May," the challengers pitched three green pavilions in a fair plain between Calais and the Abbey of Saint Inglebert. Two shields hung before each pavilion, with the arms of the owner.

"On the 21st of the month of May, as it had been proclaimed, the three knights were properly armed, and their horses properly saddled, according to the laws of the tournament. On the same day those knights who were in Calais sallied forth, either as spectators or tilters, and, being arrived at the spot, drew up on one side. The place of the tournament was smooth, and green with grass.

"Sir John Holland was the first who sent his squire to touch the war-target of Sir Bouçicaut, who instantly issued from his pavilion completely armed. Having mounted his horse, and grasped his spear, which was stiff and well steeled, they took their distances. When the two knights had for a short time eyed each other, they spurred their horses, and met full gallop with such a force that Sir Bouçicaut pierced the shield of the Earl of Huntingdon, and the point of his lance slipped along his arm, but without wounding him. The two knights, having passed, continued their gallop to the end of the list. This course was much praised. At the second course, they hit each other slightly, but no harm was done; and their horses refused to complete the third.

"The Earl of Huntingdon, who wished to continue the tilt, and was heated, returned to his place, expecting that Sir Bouçicaut would call for his lance; but he did not, and showed plainly he would not that day tilt more with the earl. Sir John Holland, seeing this, sent his squire to touch the war-target of the Lord de Saimpi. This knight, who was waiting for the combat, sallied out from his pavilion, and took his lance and shield. When the earl saw he was ready, he violently spurred his horse, as did the Lord de Saimpi. They couched their lances, and pointed them at each other. At the onset, their horses crossed; notwithstanding which, they met; but by this crossing, which was blamed, the earl was unhelmed. He returned to his people, who soon re-helmed him; and having resumed their lances, they met full gallop, and hit each other with such a force in the middle of their shields, that they would have been unhorsed had they not kept tight seats by the pressure of their legs against their horses' sides. They went to the proper places, where they refreshed themselves, and took breath.

"Sir John Holland, who had a great desire to shine at this tournament, had his helmet braced, and re-grasped his spear; when the Lord de Saimpi, seeing him advance on the gallop, did not decline meeting, but, spurring his horse on instantly, they gave blows on their helmets, that were luckily of well-tempered steel, which made sparks of fire fly from them. At this course, the Lord de Saimpi lost his helmet; but the two knights continued their career, and returned to their places.

"This tilt was much praised, and the English and French said, that the Earl of Huntingdon, Sir Bouçicaut, and the Lord de Saimpi, had excellently well justed, without sparing or doing themselves any damage. The earl wished to break another lance in honour of his lady, but it was refused him. He then quitted the lists to make room for others, for he had run his six lances with such ability and courage as gained him praise from all sides." (Johnes's *Froissart*, vol. iv. p. 143.)

The other justs were accomplished with similar spirit. Sir Peter Courtney, Sir John Russell, Sir Peter Sherburn, Sir William Clifton, and other English knights, sustaining the honour of their country against the French, who behaved with the greatest gallantry; and the whole was regarded as one of the most gallant enterprises which had been fulfilled for some time.

Besides these dangerous amusements, the unsettled and misruled state of things during the feudal times found a gentle knight anxious to support the oppressed and to put down injustice, and, agreeably to his knightly vow, frequent opportunities to exercise himself in the use of arms. There was everywhere to be found oppressors to be chastised, and evil customs to be abolished; and the knight's occupation not only permitted, but actually bound him to volunteer his services in such cases. We shall err greatly if we suppose that the adventures told in romance are as fictitious as its magic, its dragons, and its fairies. The machinery was indeed imaginary, or rather, like that of Homer, it was grounded on the popular belief of the times. But the turn of incidents resembled, in substance, those which passed almost daily under the eye of the narrator. Even the stupendous feats of prowess displayed by the heroes of these tales, against the most overwhelming odds, were not without parallel in the history of the times. When men fought hand to hand, the desperate exertions of a single champion, well mounted and armed in proof, were sometimes sufficient to turn the fate of a disputed day; and the war-cry of a well-known knight struck terror farther than his arms. The advantage possessed by such an invulnerable champion over the half-naked infantry of the period, whom he might pursue and cut down at his pleasure, was so great, that in the insurrection of the peasants called the *Jâcquerie*, the Earl of Foix and the Captal de Buche, their forces not being nearly as one to ten, hesitated not to charge these disorderly insurgents with their men-at-arms, and were supposed to have slain nearly seven thousand, following the execution of the fugitives with as little mercy as the peasants had showed during the brief success of their rebellion.

The right which crown vassals claimed and exercised, of imposing exorbitant tolls and taxes within their domains, was often resisted by the knights-errant of the day, whose adventures in fact approached much nearer to Don Quixote than perhaps our readers are aware of. For although the knight of La Mancha was perhaps two centuries too late in exercising his office of redresser of wrongs, and although his heated imagination confounded ordinary objects with such as were immediately connected with the exercise of chivalry, yet, at no great distance from the date of the inimitable romance of Cervantes, real circumstances occurred of a nature nearly as romantic as the achievements which Don Quixote aspired to execute. In the more ancient times, the wandering knight could not go far without finding some gentleman oppressed by a powerful neighbour, some captive immured in a feudal dungeon, some orphan deprived of his heritage, some traveller pillaged, some convent or church violated, some lady in need of a champion, or some prince engaged in a war with a powerful adversary; all of which incidents furnished fit occasion for the exercise of his valour. By degrees, as order became more generally established, and the law of each state began to be strong enough for the protection of the subject, the interference of these self-authorized and self-dependent champions, who, besides, were in all probability neither the most judicious nor moderate, supposing them to be equitable, mediators, became a nuisance rather than an assistance to civil society; and undoubtedly this tended to produce those distinctions in the order of knighthood which we are now to notice.

Different orders of knighthood.

The most ancient, and originally the sole order of knighthood, was that of the knight-bachelor. This was the proper degree conferred by one knight on another, without the interference either of prince, noble, or churchman; and its privileges and duties approached nearly to those of the knight-errant. Were it possible for human nature to have acted up to the pitch of merit required by the statutes of chivalry, this order might have proved for a length of time a substitute for imperfect policy, a remedy against feudal tyranny, a resource for the weak when oppressed by the strong. Unquestionably, in many individual instances, knights were all that we have described them. But the laws of chivalry, like those of the ascetic orders, while announcing a high tone of virtue and self-denial, unfortunately afforded the strongest temptations to those who professed its vows, to abuse the character which they assumed. The degree of knighthood was easily attained, and did not subject the warrior on whom it was

granted to any particular tribunal in case of his abusing the powers which it conferred. Thus the knight became, in many instances, a wandering and licentious soldier, carrying, from castle to castle, and from court to court, the offer of his mercenary sword, and frequently abusing his character, to oppress those whom his oath bound him to protect. The license and foreign vices imported by those who had returned from the crusades, the poverty also to which noble families were reduced by these fatal expeditions, all aided to throw the quality of knight-bachelor lower in the scale of honour, when unsupported by birth, wealth, or the command of followers.

The poorest knight-bachelor, however, long continued to exercise the privileges of the order Their title of bachelor (or *bas chevalier*, according to the best derivation) marked that they were early held in inferior estimation to those more fortunate knights who had extensive lands and numerous vassals. They either attached themselves to the service of some prince or rich noble, and were supported at their expense, or they led the life of mere adventurers. There were many knights who, like Sir Gaudwin in the romance of *Partenopex de Blois*, subsisted by passing from one court, camp, and tournament, to another, and contrived even, by various means open to persons of that profession, to maintain, at least for a time, a fair and goodly appearance.

> So riding, they o'ertake an errant knight
> Well horsed, and large of limb, Sir Gaudwin hight;
> He nor of castle nor of land was lord,
> Houseless he reap'd the harvest of the sword:
> And now, not more on fame than profit bent,
> Rode with blythe heart unto the tournament,
> For cowardice he held it deadly sin,
> And sure his mind and bearing were akin.
> The face an index to the soul within,
> It seem'd that he, such pomp his train bewray'd,
> Had shap'd a goodly fortune by his blade;
> His knaves were, point device, in livery dight,
> With sumpter-nags, and tents for shelter in the night.

These bachelor-knights, as Mr Rose has well described Sir Gaudwin, set their principal store by valour in battle; and perhaps it was the only quality of chivalry which they at all times equally prized and possessed. Their boast was to be the children of war and battle, living in no other atmosphere but what was mingled with the dust of conflict and the hot breath of charging steeds. A "gentle bachelor" is so described in one of the *Fabliaux* translated by Mr Way:

> What gentle bachelor is he,
> Sword-begot in fighting field,
> Rock'd and cradled in a shield,
> Whose infant food a helm did yield.

His restless gallantry in tournament and battle—the rapidity with which he traversed land and sea, from England to Switzerland, to be present at each remarkable occasion of action—with his hardihood in enduring every sort of privation—and his generosity in rewarding minstrels and heralds—his life of battle and turmoil—and his deeds of strength and fame—are all enumerated. But we hear nothing of his redressing wrongs, or of his protecting the oppressed. The knight-bachelor, according to this picture, was a valiant prize-fighter, and lived by the exercise of his weapons.

In war, the knight-bachelor had an opportunity of maintaining, and even of enriching himself, if fortunate, by the ransom of such prisoners as he happened to make in battle. If in this way he accumulated wealth, he frequently employed it in levying followers, whose assistance, with his own, he hired out to such sovereigns as were willing to set a sufficient price on his services. In time of peace, the tournaments afforded, as we have already observed, a certain means of income to these adventurous champions. The horses and arms of the knights who succumbed on such occasions were forfeited to the victors, and these the wealthy were always willing to reclaim by a payment in money. At some of the achievements in arms the victors had the right, by the conditions of the encounter, to impose severe terms on the vanquished, besides the usual forfeiture of horse and armour. Sometimes the unsuccessful combatant ransomed himself from imprisonment, or other hard conditions, by a sum of money; a transaction in which the knight-bachelors, such as we have described them, readily engaged. These adventurers used to call the sword which they used in tourneys their *gagne-pain*, or bread-winner, as itinerant fiddlers of our days denominate their instruments.

> Dont i est gagne-pain nommée
> Car par li est gagnies li pains.
> *Pelerinage du Monde*, par Guigneville.

Men of such roving and military habits, subsisting by means so precarious, and lying under little or no restraint from laws, or from the social system, were frequently dangerous and turbulent members of the commonwealth. Every usurper, tyrant, or rebel, found knights-bachelors to espouse his cause, in numbers proportioned to his means of expenditure. They were precisely the "landless resolutes," whom any adventurer of military fame or known enterprise could easily collect

> For food and diet to some enterprise
> That hath a stomach in't.

Sometimes knights were found who placed themselves directly in opposition to all law and good order, headed independent bands of depredators, or, to speak plainly, of robbers, seized upon some castle as a place of temporary retreat, and laid waste the country at their pleasure. In the disorderly reigns of Stephen and of King John, many such leaders of banditti were found in England. And France, in the reign of John and his successors, was almost destroyed by them. Many of these leaders were knights or squires, and almost all pretended that in their lawless license they only exercised the rights of chivalry, which permitted, and even enjoined, its votaries to make war without any authority but their own, whenever a fair cause of quarrel occurs.

These circumstances brought the profession of knight-bachelor into suspicion, as in other cases the poverty of those who held the honour exposed it to contempt in their person. The sword did not always reap a good harvest; an enterprise was unfortunate, or a knight was discomfited. In such circumstances he was obliged to sell his arms and horse, and endure all the scorn which is attached to poverty. In the beautiful lay of Lanval, and in the corresponding tale of Gruelan, the story opens with the picture of the hero reduced to indigence, dunned by his landlord, and exposed to contempt by his beggarly equipment. And when John de Vienne and his French men-at-arms returned from Scotland, disgusted with the poverty and ferocity of their allies, without having had any opportunity to become wealthy at the expense of the English, and compelled before their departure to give satisfaction for the insolencies which they committed towards the inhabitants, "divers knights and squires had passage and so returned, some into Flanders, and as wind and weather would drive them, without horse and harness, right poor and feeble, cursing the day that ever they came into Scotland, saying that never man had so hard a voyage." (Berner's *Froissart*, vol. ii. (reprint) p. 32.) The frequent prohibition of tournaments, both by the church and by the more peaceful sovereigns, had also its necessary effect in impoverishing the knights-bachelors, to whom,

Chivalry. as we have seen, these exhibitions afforded one principal means of subsistence. This is touched upon in one of the French *fabliaux*, as partly the cause of the poverty of a chevalier, whose distresses are thus enumerated:

> Listen, gentles, while I tell
> How this knight in fortune fell:
> Lands nor vineyards had he none,
> Justs and war his living won;
> Well on horseback could he prance,
> Boldly could he break a lance,
> Well he knew each warlike use;
> But there came a time of truce,
> Peaceful was the land around,
> Nowhere heard a trumpet sound,
> Rust the shield and faulchion hid,
> Just and tourney were forbid,
> All his means of living gone,
> Ermine mantle had he none,
> And in pawn had long been laid
> Cap and mantle of brocade,
> Harness rich and charger stout,
> All were eat and drunken out.[1]

As the circumstances which we have mentioned tended to bring the order of knight-bachelor in many instances into contempt, the great and powerful attempted to entrench themselves within a circle which should be inaccessible to the needy adventurers whom we have described. Hence the institution of knights-banneret was generally received.

Knights-banneret. The distinction betwixt the knight-banneret and the knight-bachelor was merely in military rank and precedence, and the former may rather be accounted an institution of policy than of chivalry. The bachelor displayed, or was entitled to display, a pennon or forked ensign. The knight-banneret had the right of raising a proper *banner*, from which his appellation was derived. He held a middle rank beneath the barons or great feudatories of the crown, and above the knights-bachelors. The banner from which he took his title was a flag squared at the end, which, however, in strictness, was oblong, and not an exact square on all the sides, which was the proper emblem of a baron. Du Tillet reports, that the Count de Laval challenged Sir Raoul de Couequens' right to raise a square banner, being a banneret, and not a baron; and adds, that he was generally ridiculed for this presumption, and called the knight with the square ensign. The circumstance of the encroachment plainly shows, that the distinction was not absolutely settled; nor have we found the ensign of the bannerets anywhere described, except as being generally a square standard. Indeed, it was only the pennon of the knight a little altered; for he who aspired to be a banneret received no higher gradation in chivalry, as attached to his person, and was inducted into his new privileges merely by the commander-in-chief, upon the eve of battle, cutting off the swallow-tail or forked termination of the pennon.

In the appendix to Joinville's *Memoirs*, there is an essay on the subject of the bannerets, in which the following account of them is quoted from the ancient book of Ceremonies:—

"Comme un bachelier peut lever banniere, et devenir banneret.

"Quant un bachelier a grandement servi et suivy la guerre, et que il a assez terre, et que 'il puisse avoir gentilshommes, ses hommes, et pour accompagner sa banniere, il peut licitement lever banniere, et non autrement. Car nul homme ne doit porter ne lever banniere en bataille, s'il n'a du moins cinquante hommes d'armes, tous ses hommes et les archiers et arbalestriers qui y appartiennent. Et s'il les a 'il doit à la première bataille, ou il se trouvera, apporter un pennon de ses armes, et doit venir au connestable, ou aux marischaux, ou à celui qui sera lieutenant de l'ost pour le prince, requirer qu'il porte banniere; et s'il lui octroient, doit sommer les heraux pour tesmoignage, et doivent couper la queüe du pennon, et alors le doit porter et lever avant les autres bannieres, au dessoubs des autres barons.

There is this same ceremonial, in a chapter respecting the banneret, in these terms:—

"Comme se doit maintenir un banneret en bataille.

"Le banneret doit avoir cinquante lances, et les gens de trait qui y appartiennent: c'est à savoir les xxv. pour lui, et sa banniere garder. Et doit estre sa banniere dessoubs des barons. Et s'il y a autres banniere, ils doivent mettre leurs bannieres à l'onneur, chacun selon son endroit, et pareillement tout homme qui porte banniere."

Froissart, always our best and most amusing authority, gives an account of the manner in which the celebrated Sir John Chandos was made banneret by the Black Prince, before the battle of Navarete. The whole scene forms a striking picture of an army of the middle ages moving to battle. Upon the pennons of the knights, penoncels of the squires, and banners of the barons and bannerets, the army formed, or, in modern phrase, dressed its line. The usual word for the attack was, "Advance banners, in the name of God and Saint George."

"When the sun was risen, it was a beautiful sight to view these battalions, with their brilliant armour glittering with its beams. In this manner they nearly approached to each other. The prince, with a few attendants, mounted a small hill, and saw very clearly the enemy marching straight towards them. Upon descending this hill, he extended his line of battle in the plain, and then halted.

"The Spaniards, seeing the English had halted, did the same, in order of battle; then each man tightened his armour, and made ready as for instant combat.

"Sir John Chandos advanced in front of the battalions, with his banner uncased in his hand. He presented it to the prince, saying, 'My Lord, here is my banner; I present it to you, that I may display it in whatever manner shall be most agreeable to you; for, thanks to God, I have now sufficient lands that will enable me so to do, and maintain the rank which it ought to hold.'

"The prince, Don Pedro being present, took the banner in his hands, which was blazoned with a sharp stake gules, on a fixed argent; after having cut off the tail to make it square, he displayed it, and returning it to him by the handle, said, 'Sir John, I return you your banner; God give you strength and honour to preserve it.'

"Upon this, Sir John left the prince, went back to his men, with the banner in his hand,—'Gentlemen, behold my banner and yours; you will therefore guard it as it becomes you.' His companions, taking the banner, replied with much cheerfulness, that 'if it pleased God and St George, they would defend it well, and act worthily of it, to the utmost of their abilities.'

"The banner was put into the hands of a worthy English squire, called William Allestry, who bore it with honour that day, and loyally acquitted himself in the service. The English and Gascons soon after dismounted on the heath, and assembled very orderly together, each lord under his banner or pennon, in the same battle-array as when they passed the mountains. It was delightful to see and examine these banners and pennons, with the noble army that was under them."

It should not be forgotten, that Sir John Chandos exerted himself so much to maintain his new honour, that, advancing too far among the Spaniards, he was unhorsed,

[1] See the original in the republication of Barbazan's *Fabliaux*, vol. iii. p. 410.

and having grappled with a warrior of great strength, called Martin Ferrand, he fell undermost, and must have been slain, had he not bethought him of his dagger, with which he stabbed his gigantic antagonist. (Johnes's *Froissart*, vol. i. p. 731.)

A banneret was expected to bring into the field at least thirty men-at-arms, that is, knights or squires mounted, and in complete order, at his own expense. Each man-at-arms, besides his attendants on foot, ought to have a mounted crossbow-man, and a horseman armed with a bow and axe. Therefore the number of horsemen alone who assembled under a banner was at least three hundred, and, including followers on foot, might amount to a thousand men. The banneret might indeed have arrayed the same force under a pennon; but his accepting a banner bound him to bring out that number at least. There is no room, however, to believe that these regulations were very strictly observed.

In the reign of Charles VII. the nobles of France made a remonstrance to the king, setting forth that their estates were so much wasted by the long and fatal wars with England, that they could no longer support the number of men attached to the dignity of banneret. The companies of men-at-arms, which had hitherto been led by knights of that rank, and the distinction between knights-bannerets and knights-bachelors, were altogether disused from that period.[1] In England the title survived, but in a different sense. Those who received knighthood in a field of battle, where the royal standard was displayed, were called knights-banneret. Thus King Edward VI. notices in his *Journal*, that after the battle of Pinkie, " Mr Brian Sadler and Vane were made bannerets."

Companions in arms.

The distinction of banneret was not the only subdivision of knighthood. The special privileged fraternities, orders, or associations of knights, using a particular device, or embodied for a particular purpose, require also to be noticed. These might in part be founded upon the union which knights were wont to enter into with each other as " companions in arms," than which nothing was esteemed more sacred. The partners were united for weal and woe, and no crime was accounted more infamous than to desert or betray a companion at arms. They had the same friends and the same foes; and as it was the genius of chivalry to carry every virtuous and noble sentiment to the most fantastic extremity, the most extravagant proofs of fidelity to this engagement were often exacted or bestowed. The beautiful romance of *Ames and Amelien*, in which a knight slays his own child to make a salve with its blood, to cure the leprosy of his brother in arms, turns entirely on this extravagant pitch of sentiment.

To this fraternity only two persons could, with propriety, bind themselves. But the various orders, which had in view particular objects of war, or were associated under the authority of particular sovereigns, were also understood to form a bond of alliance and brotherhood amongst themselves.

The great orders of the Templars and Knights-Hospitallers of Saint John of Jerusalem, as well as that of the Teutonic Knights, were military associations, formed, the former for defence of the Holy Land, and the latter for conversion (by the edge of the sword, of course) of the Pagans in the north of Europe. They were managed by commanders or superintendents, and by a grand master, forming a sort of military republic, the individuals of which were understood to have no distinct property or interest from the order in general. But the system and history of these associations will be found under the proper heads. It is here only necessary to notice them as subdivisions of the knighthood or chivalry of Europe.

Other subdivisions arose from the various associations, also called orders, formed by the different sovereigns of Europe, not only for the natural purpose of drawing around their persons the flower of knighthood, but often with political views of much deeper import. The romances which were the favourite reading of the time, or which, at least, like the servant in the comedy, the nobles " had read to them," and which were on all occasions quoted gravely, as the authentic and authoritative records of chivalry, afforded the most respectable precedents for the formation of such fraternities under the auspices of sovereign princes; the Round Table of King Arthur, and the Paladins of Charlemagne, forming cases strictly in point. Edward III., whose policy was equal to his love of chivalry, failed not to avail himself of these precedents, not only for the exaltation of military honour and exercise of warlike feats, but questionless that he might draw around him, and attach to his person, the most valiant knights from all quarters of Europe. For this purpose, in the year 1344, he proclaimed, as well in Scotland, France, Germany, Hainault, Spain, and other foreign countries, as in England, that he designed to revive the Round Table of King Arthur, offering free conduct and courteous reception to all who might be disposed to attend the splendid justs to be held upon that occasion at Windsor Castle. This solemn festival, which Edward proposed to render annual, excited the jealousy of Philip de Valois, king of France, who not only prohibited his subjects to attend the Round Table at Windsor, but proclaimed an opposite Round Table to be held by himself at Paris. In consequence of this interference the festival of Edward lost some part of its celebrity, and was diminished in splendour and frequency of attendance. This induced King Edward to establish the memorable Order of the Garter. Twenty-six of the most noble knights of England and Gascony were admitted into this highly honourable association, the well-known motto of which (*Honi soit qui mal y pense*) seems to apply to the misrepresentations which the French monarch might throw out respecting the Order of the Garter, as he had already done concerning the festival of the Round Table. There was so much dignity, as well as such obvious policy, in selecting from the whole body of chivalry a select number of champions, to form an especial fraternity under the immediate patronage of the sovereign,—it held out such a powerful stimulus to courage and exertion to all whose eyes were fixed on so dignified a reward of ambition,—that various orders were speedily formed in the different courts of Europe, each having its own peculiar badges, emblems, and statutes. To enumerate these is the task of the herald, not of the historian, who is only called upon to notice their existence and character. The first effect of these institutions on the spirit of chivalry in general was doubtless favourable, as holding forth to the knighthood a high and honourable prize of emulation. But when every court in Europe, however petty, had its own peculiar order and ceremonial, while the great potentates established several, these dignities became so common as to throw into the shade the order of knights-bachelors, the parent and proper degree of chivalry, in comparison to which the others were mere innovations. The last distinction introduced, when the spirit of chivalry was almost totally extinguished, was the degree of knight-baronet.

Baronet.

The degree of baronet, or hereditary knighthood, might have been with greater propriety termed an inferior rank of noblesse than an order of chivalry. Nothing can be more

[1] See the works of Pasquier, Du Tillet, Le Gendre, and other French antiquaries.

Chivalry. alien from the original idea of chivalry than that knighthood could be bestowed on an infant, who could not have deserved the honour, or be capable of discharging its duties. But the way had been already opened for this anomaly by the manner in which the orders of foreign knighthood had been conferred upon children and infants in nonage. Some of these honours were also held by right of blood, the Dauphin of France, for example, being held to be born a knight of the Holy Ghost without creation; and men had already long lost sight of the proper use and purpose of knighthood, which was now regarded and valued only as an honorary distinction of rank, that imposed no duties, and required no qualifications, or period of preliminary noviciate. The creation of this new dignity, as is well known, was a device of James I. to fill those coffers which his folly and profusion had emptied; and although the pretext of a Nova Scotia or of an Ulster settlement was used as the apology for the creation of the order, yet it was perfectly understood that the real value given was the payment of a certain sum of money. The cynical Osborne describes this practice of the sale of honours, which, in their origin, were designed as the reward and pledge of chivalrous merit, with satirical emphasis.

"At this time the honour of knighthood, which antiquity reserved sacred as the cheapest and readiest jewel to present virtue with, was promiscuously laid on any head belonging to the yeomandry (made addle through pride and a contempt of their ancestor's pedigree), that had but a court friend, or money to purchase the favour of the meanest able to bring him into an outward roome, when the king, the fountaine of honour, came downe, and was uninterrupted by other businesse; in which case it was then usuall for him to grant a commission for the chamberlaine or some other lord to do it."

Degradation. Having noticed the mode in which knighthood was conferred, and the various subdivisions of the order in general, it is proper to notice the mode in which a knight might be degraded from his rank. This forfeiture might take place from crimes either actually committed, or presumed by the law of arms. The list of crimes for which a knight was actually liable to degradation corresponded to his duties. As devotion, the honour due to ladies, valour, truth, and loyalty, were the proper attributes of chivalry, so heresy, insults or oppression of females, cowardice, falsehood, or treason, caused his degradation. And heraldry, an art which might be said to bear the shield of chivalry, assigned to such degraded knights and their descendants peculiar bearings, called in blazonry abatements, though it may be doubted if these were often worn or displayed.

The most common case of a knight's degradation occurred in the appeal to the judgment of God by the single combat in the lists. In the appeal to this awful criterion, the combatants, whether personally concerned or appearing as champions, were understood, in martial law, to take on themselves the full risk of all consequences; and as the defendant or his champion, in case of being overcome, was subjected to the punishment proper to the crime of which he was accused, so the appellant, if vanquished, was, whether a principal or substitute, condemned to the same doom to which his success would have exposed the accused. Whichever combatant was vanquished, he was liable to the penalty of degradation; and if he survived the combat, the disgrace to which he was subjected was worse than death. His spurs were cut off close to his heels with a cook's cleaver; his arms were bafted and reversed by the common hangman; his belt was cut to pieces, and his sword broken. Even his horse showed his disgrace, the animal's tail being cut off close to the rump, and thrown on a dunghill. The death-bell tolled, and the funeral service was said, for a knight thus degraded, as for one dead to knightly honour. And if he fell in the appeal to the judgment of God, the same dishonour was done to his senseless corpse. If alive, he was only rescued from death to be confined in the cloister. Such at least were the strict rules of chivalry, though the courtesy of the victor, or the clemency of the prince, might remit them in favourable cases. Chivalry.

Knights might also be degraded without combat, when convicted of a heinous crime. In Stowe's *Chronicle*, we find the following minute account of the degradation of Sir Andrew Harclay, created Earl of Carlisle by Edward II., but afterwards accused of traitorous correspondence with Robert the Bruce, and tried before Sir Anthony Lucy.

"He was ledde to the barre as an earle morthily apparelled, with his sword girt about him, horsed, booted, and spurred, and unto whom Sir Anthony spake in this manner. Sir Andrew (quoth he), the king, for thy valiant service, hath done thee great honour, and made thee Earle of Carlile; since which tyme, thou, as a traytor to thy lord the king, leddest his people, that shoulde have holpe him at the battell of Heighland, awaie by the county of Copland, and through the earledom of Lancaster, by which meanes, our lorde the king was discomfitted there of the Scottes, through thy treason and falsenesse; whereas, if thou haddest come betimes, he hadde had the victorie: and this treason thou committedst for y^e great summe of golde and silver that thou receivedst of James Dowglasse, a Scot, the king's enemy. Our lord the king will, therefore, that the order of knighthood, by the which thou receivedst all thine honour and worship uppon thy bodie, be brought to nought, and thy state undone, that other knights, of lower degree, may after thee beware, and take example truely to serve.

"Then commanded he to hesne his spurres from his heeles, then to break his sword over his head, which the king had given him to keepe and defend his land therewith, when he made him earle. After this, he let unclothe him of his furred tabard, and of his hoode, of his coate of armes, and also of his girdle; and when this was done, Sir Anthony sayde unto him, Andrewe (quoth he), now art thou no knight, but a knave; and, for thy treason, the king will that thou shalt be hanged and drawne, and thyne head smitten off from thy bodie, and burned before thee, and thy bodie quartered: and thy head being smitten off, afterwarde to be set upon London bridge, and thy foure quarters shall be sent into foure good townes of England, that all other may beware by thee. And as Anthony Lucy hadde sayde, so was it done in all things, on the last daie of October."

III. We are arrived at the third point proposed in our arrangement, the causes, namely, of the decay and extinction of chivalry. Decay of chivalry.

The spirit of chivalry sunk gradually under a combination of physical and moral causes; the first arising from the change gradually introduced into the art of war, and the last from the equally great alteration produced by time in the habits and modes of thinking in modern Europe. Chivalry began to dawn in the end of the tenth and beginning of the eleventh century. It blazed forth with high vigour during the crusades, which indeed may be considered as exploits of national knight-errantry, or general wars, undertaken on the very principles which actuated the conduct of individual knights adventurers. But its most brilliant period was during the wars between France and England; and it was unquestionably in those kingdoms that the habit of constant and honourable opposition, unembittered by rancour or personal hatred, gave the fair-

est opportunity for the exercise of the virtues required from him whom Chaucer terms a very perfect gentle knight. Froissart frequently makes allusions to the generosity exercised by the French and English to their prisoners, and contrasts it with the dungeons to which captives taken in war were consigned, both in Spain and Germany. Yet both these countries, and indeed every kingdom in Europe, partook of the spirit of chivalry in a greater or less degree; and even the Moors of Spain caught the emulation, and had their orders of knighthood as well as the Christians. But, even during this splendid period, various causes were silently operating the future extinction of the flame, which blazed thus wide and brightly.

An important discovery, the invention of gunpowder, had taken place, and was beginning to be used in war, even when chivalry was in its highest glory. It is said Edward III. had field-pieces at the battle of Cressy, and the use of guns is mentioned even earlier. But the force of gunpowder was long known and used ere it made any material change in the art of war. The long-bow continued to be the favourite, and it would seem the more formidable missile weapon, for well nigh two centuries after guns had been used in war. Still every successive improvement was gradually rendering the invention of fire-arms more perfect, and their use more decisive of the fate of battle. In proportion as they came into general use, the suits of defensive armour began to be less generally worn. It was found, that these cumbrous defences, however efficient against lances, swords, and arrows, afforded no effectual protection against these more forcible missiles. The armour of the knight was gradually curtailed to a light head-piece, a cuirass, and the usual defences of men-at-arms. Complete harness was only worn by generals and persons of high rank, and that rather, it would seem, as a point of dignity than for real utility. The young nobility of France, especially, tired of the unwieldy steel coats in which their ancestors sheathed themselves, adopted the slender and light armour of the German Reiters or mercenary cavalry. They also discontinued the use of the lance; in both cases contrary to the injunctions of Henry IV. and the opinion of Sully. At length, the arms of the cavalry were changed almost in every particular from those which were proper for chivalry; and as, in such cases, much depends upon outward show and circumstance, the light-armed cavalier, who did not carry the weapons or practise the exercises of knighthood, laid aside, at the same time, the habits and sentiments peculiar to the order.

Another change of vital importance arose from the institution of the bands of gens-d'armes or men-at-arms in France, constituted, as we have observed, expressly as a sort of standing army, to supply the place of bannerets, bachelors, squires, and other militia of early times. It was in the year 1445 that Charles VII. selected, from the numerous chivalry of France, fifteen companies of men-at-arms, called Les Compagnies d'Ordonnance, to remain in perpetual pay and subordination, and to enable the sovereign to dispense with the services of the tumultuary forces of chivalry which, arriving and departing from the host at pleasure, collecting their subsistence by oppressing the country, and engaging in frequent brawls with each other, rather weakened than aided the cause they professed to support. The regulated companies, which were substituted for these desultory bands, were of a more permanent and manageable description. Each company contained a hundred men-at-arms, and each man-at-arms was to be what was termed a *lance garnie*, that is, a mounted spearman, with his proper attendants, being four archers, and a varlet, called a *coustillier*. Thus, each company consisted of six hundred horse, and the fifteen bands amounted to fifteen thousand cavalry. The charge of national defence was thus transferred from the chivalry of France, whose bold and desperate valour was sometimes rendered useless by their independent wilfulness and want of discipline, to a sort of regular forces, whose officers (a captain, lieutenant, and an ensign in each company) held command, not in virtue of their knighthood or banner right, but being direct commissions from the crown, as in modern times. At first, indeed, these bands of regulated gens-d'armes were formed of the same materials as formerly, though acting under a new system. The officers were men of the highest rank; the archers, and even the varlets, were men of honourable birth. When the Emperor Maximilian proposed that the French gens-d'armes should attempt to storm Padua, supported by the German lance-knechts, or infantry, he was informed by Bayard, that if the French men-at-arms were employed, they must be supported by those of the Germans, and not by the lance-knechts, because, in the French companies of ordonnance, every soldier was a gentleman. But, in the reign of Charles IX., we find the change natural to such a new order of things was in complete operation. The king was content to seek, as qualifications for his men-at-arms, personal bravery, strength, and address in the use of weapons, without respect to rank or birth; and, probably, in many instances, men of inferior birth were preferred to fill up the ranks of these regulated bands. Monluc informs us in his *Commentaries*, that he made his first campaign, as an archer, in the Marechal de Foix's company of gens-d'armes: "A situation much esteemed in these days, when many nobles served in that capacity. At present, the rank is greatly degenerated." The complaints of the old noblesse, says Mezerai, were not without reason. Mean carabineers, they said, valets, and lacqueys, were recruited in companies, which were put on the same footing with the ancient corps of gens-d'armes, whose officers were all barons of high rank, and almost every man-at-arms a gentleman by birth. These complaints, joined with the charge against Catharine of Medicis, that she had, by the creation of twenty-five new members of the order of St Michael, rendered its honours as common as the cockle-shells on the sea-shore, serve to show how early the first rude attempt at establishing a standing and professional army operated to the subversion of the ideas and privileges of chivalry. According to La Noue, it would seem that, in his time, the practice still prevailed of sending youths of good birth to serve as pages in the gens-d'armes; but, from the sort of society with whom they mixed in service of that sort, their natural spirit was rather debased, and rendered vulgar and brutal, than trained to honour and gallantry.

Civil wars in France and England.

A more fatal cause had, however, been for some time operating in England as well as France, for the destruction of the system we are treating of. The wars of York and Lancaster in England, and those of the Huguenots and of the League, were of a nature so bitter and rancorous, as was utterly inconsistent with the courtesy, fair play, and gentleness, proper to chivalry. Where different nations are at strife together, their war may be carried on with a certain degree of moderation. "During the foreign wars between France and Spain, especially in Piedmont," says La Noue, "we might often see a body of spears pass a village, where the peasants only interrupted their village dance to offer them refreshments; and, in a little after, a hostile troop receive, from the unoffending and unoffended inhabitants, the same courtesy. The two bodies would meet and fight gallantly, and the wounded of both parties would be transferred to the same village, lodged in the same places of accommodation, receive the same attention, and rest peaceably on each other's good faith till again able to take the field." He contrasts this

generosity with the miserable oppression of the civil wars, carried on by murdering, burning, and plundering friend and foe, armed and unarmed; alleging, all the while, the specious watchwords of God's honour, the king's service, the Catholic religion, the gospel, our country. In the end, he justly observes, "the soldiers become ravenous beasts, the country is rendered desert, wealth is wasted, the crimes of the great become a curse to themselves, and God is displeased." The bloody wars of the Rose in England, the execution of prisoners on each side, the fury and animosity which allowed no plea of mercy or courtesy, were scarce less destructive to the finer parts of the spirit of chivalry in England than those of the Huguenots in France.

But the civil wars not only operated in debasing the spirit of chivalry, but in exhausting and destroying the particular class of society from which its votaries were drawn. To be of noble birth was not indeed absolutely essential to receiving the honour of knighthood, for men of low descent frequently attained it; but it required a distinguished display of personal merit to raise them out of the class where they were born; and the honours of chivalry were, generally speaking, appropriated to those of fair and gentle parentage. The noble families, therefore, were the source from which chivalry drew recruits; and it was upon the nobles that the losses, proscriptions, and forfeitures of the civil wars chiefly fell. We have seen that in France their poverty occasioned their yielding up the privilege of military command to the disposal of the crown. In England it was fortunately not so much the crown as the commons who rose on the ruins of feudal chivalry; but it is well known that the civil wars had so exhausted the English nobility, as to enable Henry VII. to pass his celebrated statutes against those hosts of retainers, which struck, in fact, at the very root of their power. And thus Providence, whose ways bring good out of evil, laid the foundation of the future freedom of England in the destruction of what had long been its most constitutional ground of defence, and in the subjugation of that system of chivalry which, having softened the ferocity of a barbarous age, was now to fall into disuse, as too extravagant for an enlightened one.

Change of manners.

In fact, it was not merely the changes which had taken place in the constitution of armies and fashion of the fight, nor the degraded and weak state of the nobles, but also, and in a great degree, the more enlightened manners of the times, and the different channels into which enthusiasm and energy were directed, which gradually abolished the sentiments of chivalry. We have seen that the abstract principles of chivalry were, in the highest degree, virtuous and noble, nay, that they failed by carrying to an absurd, exaggerated, and impracticable point, the honourable duties which they inculcated. Such doctrines, when they fail to excite enthusiasm, become exploded as ridiculous. Men's minds were now awakened to other and more important and complicated exercises of the understanding, and were no longer responsive to the subjects which so deeply interested their ancestors of the middle ages. Sciences of various kinds had been rekindled in the course of the sixteenth century; the arts had been awakened in a style of perfection unknown even to classical ages. Above all, religion had become the interesting study of thousands; and the innovating doctrines of the reformers, while hailed with ecstacy by their followers, rejected as abominations by the Catholics, and debated fiercely by both parties, involved the nobility of Europe in speculations very different from the *arrets* of the court of love, and demanded their active service in fields more bloody than those of tilt and tournament. When the historians or disputants on either side allude to the maxims of chivalry, it is in terms of censure and ridicule; yet, if we judge by the most distinguished authorities on either side, the reformers rejected as sinful what the Catholics were contented to brand as absurd. It is with no small advantage to the Huguenots,—to that distinguished party which produced Sully, D'Aubigné, Coligni, Duplessis-Mornay, and La Noue, that we contrast the moral severity with which they pass censure on the books of chivalry, with the licentious flippancy of Brantome, who ridicules the same works on account of the very virtues which they inculcate. From the books of *Amadis de Gaul*, refining, as he informs us, upon the ancient vanities of Perceforest, Tristan, Giron, &c., La Noue contends, the age in which he lived derived the recommendation and practice of incontinence, of the poison of revenge, of neglect of sober and rational duty, desperate blood-thirstiness, under disguise of search after honour, and confusion of public order. "They are instructions," he says, "of Apollyon, who, being a murtherer from the beginning, delighteth wholly in promoting murther." "Of the tournaments," he observes that "such spectacles, rendering habitual the sight of blows and blood, had made the court of France pitiless and cruel." "Let those," he exclaims, "who desire to feed their eyes with blood, imitate the manner of England, where they exercise their cruelty on brute beasts, bringing in bulls and bears to fight with dogs, a practice beyond comparison far more lawful than the justs of chivalry."[1]

It is curious to contrast the opinions of La Noue, a stern and moral reformer, and a skilful and brave soldier as France ever produced, although condemning all war that did not spring out of absolute necessity, with those of Brantome, a licentious courtier, who mixed the popish superstitions, which stood him instead of religion, with a leaven of infidelity and blasphemy. From the opinions he has expressed, and from what he has too faithfully handed down as the manners of his court and age, it is plain that all which was valuable in the spirit of chivalry had been long renounced by the French noblesse. To mark this declension, it is only necessary to run over the various requisites already pointed out as necessary to form the chivalrous character, and contrast them with the opinions held in the end of the sixteenth century, in the court of the descendants of Saint Louis.

The spirit of devotion which the rules of chivalry inculcated was so openly disavowed, that it was assigned as a reason for preferring the character of Sir Tristram to that of Sir Lancelot, that the former is described in romance as relying, like Mezentius, upon his own arm alone; whereas Lancelot, on engaging in fight, never failed to commend himself to God and the saints, which, in the more modern opinions of the gallants of France, argued a want of confidence in his own strength and valour.

The devotion with which the ancient knights worshipped the fair sex was held to be as old-fashioned and absurd as that which they paid to heaven. The honours paid to chastity and purity in the German forests, and transferred as a sacred point of duty to the sons of chivalry, were as little to be found in the court of France, according to Brantome, as the chastity and purity to which it was due. The gross and coarse sensuality which we have seen engrafted upon professions of Platonic sentiment, became finally so predominant, as altogether to discard all marks of sentimental attachment; and from the time of Catharine of Medicis, who trained her maids of honour as courtezans, the manners of the court of France seem to have been inferior in decency to those of a well-regulated bagnio. The sort of respect which these ladies were deemed

[1] *Discourses, Political and Military*, translated out of the French of La Noue, 1587.

entitled to may be conjectured by an anecdote given by Lord Herbert of Cherbury, whose own character was formed upon the chivalrous model which was now become obsolete. As he stood in the trenches before a besieged place, along with Balagny, a celebrated duellist of the period, between whom and Lord Herbert some altercation had formerly occurred, the Frenchman, in a bravade, jumped over the entrenchment, and, daring Herbert to follow him, ran towards the besieged place, in the face of a fire of grape and musquetry. Finding that Herbert outran him, and seemed to have no intention of turning back, Balagny was forced to set the example of retreating. Lord Herbert then invited him to an encounter upon the old chivalrous point, which had the fairer and more virtuous mistress; to which proposition Balagny replied by a jest so coarse, as made the Englishman retort that he spoke like a mean debauchee, not like a cavalier and man of honour. As Balagny was one of the most fashionable gallants of his time, and, as the story shows, ready for the most hair-brained achievements, his declining combat upon the ground of quarrel chosen by Lord Herbert is a proof how little the former love of chivalry accorded with the gallantry of these later days.

Bravery, the indispensable requisite of the *preux chevalier*, continued, indeed, to be held in the same estimation as formerly; and the history of the age gave the most brilliant as well as the most desperate examples of it, both in public war and private encounter. But courage was no longer tempered with the good faith and courtesy, *La bonta dei gli cavalieri antichi*, so celebrated by Ariosto. There no longer existed those generous knights, that one day bound the wounds of a generous enemy, guided him to a place of refuge, and defended him on the journey, and which, on the next, hesitated not to commit itself in turn to the power of a mortal foe, without fear that he would break the faithful word he had pawned for the safety of his enemy. If such examples occur in the civil wars of France, they were dictated by the generosity of individuals who rose above the vices of their age, and were not demanded, as matters of right, from all who desired to stand well in public opinion. The intercourse with Italy, so fatal to France in many respects, failed not to imbue her nobility with the politics of Machiavel, the coarse licentiousness of Aretin, and the barbarous spirit of revenge, which held it wise to seek its gratification, not in fair encounter, but *per ogni modo*, in what manner soever it could be obtained. Duels, when they took place, were no longer fought in the lists, or in presence of judges of the field, but in lonely and sequestered places. Inequality of arms was not regarded, however great the superiority on one side. "Thou hast both a sword and dagger," said Quelus to Antragues, as they were about to fight, "and I have only a sword."—"The more thy folly," was the answer, "to leave thy dagger at home. We came to fight, not to adjust weapons." The duel accordingly went forward, and Quelus was slain, his left hand (in which he should have had his dagger) being shockingly cut in attempting to parry his antagonist's blows without that weapon. The challenged person having a right to choose his weapons, often endeavoured to devise such as should give him a decidedly unfair advantage. Brantome records with applause the ingenuity of a little man, who, being challenged by a tall Gascon, made choice of a gorget so constructed that his gigantic adversary could not stoop his neck so as to aim his blows right. Another had two swords forged of a temper so extremely brittle, that unless used with particular caution, and in a manner to which he daily exercised himself, the blade must necessarily fly in pieces. Both these ingenious persons killed their man with very little risk or trouble, and no less applause, it would seem, than if they had fought without fraud and covine. The seconds usually engaged, and when one of the combatants was slain, his antagonist did not hesitate to assist his comrade in opposing by odds him who remained. The *little French Lawyer* of Fletcher turns entirely on this incident. By a yet more direct mode of murder, a man challenged to a duel was not always sure that his enemy was not to assassinate him by the assistance of ruffians at the place of rendezvous, of which Brantome gives several instances without much censure. The plighted word of an antagonist by no means insured against treachery to the party to whom it was given. De Rosne, a gentleman well skilled in the practice and discipline of the wars, receiving a challenge from De Fargy, through the medium of a young man, who offered to pledge his word and faith for the fair conduct of his principal, made an answer which Brantome seems to approve as prudential. "I should be unwilling," he replied, "to trust my life upon a pledge on which I would not lend twenty crowns." In many cases no ceremony was used, but the nobles assassinated each other without scruple or hesitation. Brantome gives several stories of the Baron des Vitaux, and terms his detestable murders bold and brave revenges. But it would be endless to quote examples. It is enough to call to the reader's recollection the bloody secret of the massacre of St Bartholomew, which was kept by such a number of the Catholic noblemen for two years, at the expense of false treaties, promises, and perjuries innumerable, and the execution which followed on naked, unarmed, and unsuspecting men, in which so many gallants lent their willing swords.

In England, the free tone of the government, and the advantage of equal laws, administered without respect of persons, checked similar enormities, which, however, do not appear to have been thought in all cases inconsistent with the point of honour, which, if not, as in France, totally depraved from the ancient practices of chivalry, might probably have soon become so. Sir John Ayres did not hesitate to attack Lord Herbert with the assistance of his servants; and the outrage upon the person of Sir John Coventry, which gave rise to the Coventry act against cutting and maiming, evinced the same spirit of degenerate and blood-thirsty revenge. Lord Sanquhar having lost an eye in a trial of skill with a master of defence, conceived that his honour required that he should cause the poor man to be assassinated by ruffians in his own school; but as this base action met its just reward at the gallows, the spirit of Italian revenge was probably effectually checked by such a marked example. At the gallows, the unfortunate nobleman expressed his detestation for the crime, which he then saw in all its enormity. Before his trial he said the devil had so blinded his understanding that he could not understand that he had done amiss, or otherwise than befitting a man of high rank and quality, having been trained up to the court, and living the life of a soldier, which sort of men, he said, stood more on a point of honour than religion. The feelings of chivalry must have been indeed degraded, when so base an assassination was accounted a point of honour. In Scotland, the manners of which country, as is well observed by Robertson, strongly resembled those of France, the number of foul murthers during the sixteenth century was almost incredible, and indeed assassination might be termed the most general vice of the sixteenth century.

From these circumstances, the total decay of chivalrous principle is sufficiently evident. As the progress of knowledge advanced, men learned to despise its fantastic refinements; the really enlightened, as belonging to a system inapplicable to the modern state of the world; the licentious, fierce, and subtile, as throwing the barriers of

affected punctilio betwixt them and the safe, ready, and unceremonious gratification of their lust or their vengeance. The system, as we have seen, had its peculiar advantages during the middle ages. Its duties were not, and indeed could not always be performed in perfection, but they had a strong influence on public opinion; and we cannot doubt that its institutions, virtuous as they were in principle, and honourable and generous in their ends, must have done much good and prevented much evil. We can now only look back on it as a beautiful and fantastic piece of frostwork, which has dissolved in the beams of the sun. But though we look in vain for the pillars, the vaults, the cornices, and the fretted ornaments of the transitory fabric, we cannot but be sensible that its dissolution has left on the soil valuable tokens of its former existence. We do not mean, nor is it necessary to trace, the slight shades of chivalry which are yet received in the law of England. An appeal to combat in a case of treason was adjudged in the celebrated case of Ramsay and Lord Reay, in the time of Charles I. An appeal of murder seems to have been admitted as legal within a recent period, though it has subsequently been abolished by statute; but it is not in such issues, rare as they must be, that we ought to trace the consequences of chivalry. We have already shown that its effects are rather to be sought in the general feeling of respect to the female sex; in the rules of forbearance and decorum in society; in the duties of speaking truth and observing courtesy; and in the general conviction and assurance that, as no man can encroach on the property of another without accounting to the laws, so none can infringe on his personal honour, be the difference of rank what it may, without subjecting himself to personal responsibility. It will be readily believed that, in noticing the existence of duelling as a relic of chivalry, we do not mean to discuss the propriety of the custom. It is our happiness that the excesses to which this spirit is liable are checked by the laws which wisely discountenance the practice; for although the severity of the laws sometimes give way to the force of public opinion, they still remain an effectual restraint, in every case where the circumstances argue either wanton provocation or unfair advantage. It is to be hoped that, as the custom of appealing to this Gothic mode of settling disputes is gradually falling into disuse, our successors may enjoy the benefit of the general urbanity, decency, and courtesy which it has introduced into the manners of Europe, without having recourse to a remedy not easily reconciled to law or to Christianity. (W. S—TT.)

Court of CHIVALRY, a court formerly held before the lord high constable and earl marshal of England jointly, with both civil and criminal jurisdiction, but no power to enforce its decisions by fine or imprisonment, not being a court of record.

CHIVASSO, a small city of Piedmont, kingdom of Sardinia, province of Turin, in a fertile plain on the left bank of the Po, 15 miles N.E. of Turin. It was formerly considered as the key of Piedmont, and was strongly fortified, but is now only inclosed by a single wall with two gates leading to two suburbs. The front of the church of *San Pietro* is decorated with ornaments and entire statues in terra cotta, of great elegance, but much defaced. Of the ancient palace of the Counts of Montferrat, an octagonal tower still remains. Pop. 8000.

CHLAMYS, in *Antiquity*, a woollen cloak, or rather a scarf, worn by the Greeks as well as by the Oriental races with whom they were connected. It was sometimes of purple, inwrought with gold, and was the appropriate costume of military chiefs, though likewise used by other persons, by actors on the stage, and sometimes by children. It corresponded nearly to the Roman *lacerna* and *paludamentum;* and indeed the use of the chlamys itself was to some extent adopted by the Romans during the imperial period. The chlamys is frequently represented in the antique sculptures.

CHLOE, a surname of Demeter (Ceres), signifying the Blooming, under which title, as the protectress of the springing corn and grass, she was honoured by the Athenians with a festival called Chloeia, on which occasion a goat was sacrified with much mirth and rejoicing.

CHLORINE. See CHEMISTRY.

CHLORIS, in *Grecian Mythology*, the wife of Zephyrus, and the goddess of flowers, identical with the Roman Flora.

Also the name given to Melibœa, daughter of Niobe, on account of the pallor of her countenance when terror-stricken at the destruction of her brothers and sisters. See NIOBE.

Another Chloris, the daughter of Amphion of Orchomenos, was the wife of Neleus king of Pylos, and mother of Nestor.

CHLOROFORM, an article of the materia medica, used by medical men for various purposes, but principally to produce a state of anæsthesia or painlessness in surgical and obstetric operations, and in different forms of disease. *Definition.*

The fluid to which the name of chloroform is given was nearly simultaneously discovered in 1831–32 by Guthrie in America, Soubeiran in France, and Liebig in Germany. Its true chemical composition, however, was not ascertained till Dumas and Peligot directed their attention to the subject in 1834–35. *Composition.* It consists ultimately of 2 atoms of carbon, 1 of hydrogen, and 3 of chlorine. But in accordance with the generally received opinion of chemists, it may be more correctly described as composed of 3 atoms of chlorine, and 1 atom of formyle; and hence the names given to it of chloroform, chloroformyle, formychloride, or perchloride of formyle. *Origin of the name.* In other words, it is regarded as a compound of chlorine with formyle, while the latter is the hypothetic base of formic acid, or of that fluid capable of reducing the oxides of the noble metals, which Samuel Fischer long ago distilled from the body of the red ant, or *formica rufa* (hence the name formic and formyle), and which Marggraf, Arvidson, Richter, Gehlen, and others have subsequently more elaborately examined.

When Guthrie, Soubeiran, and Liebig first discovered chloroform in the course of their chemical experiments and inquiries, and when Dumas and Peligot subsequently worked out its true chemical composition, their sole and only object was the investigation of a subject in philosophical chemistry. They laboured for the pure love of the extension of knowledge; they had no idea that the substance to which they called the attention of their chemical brethren would or could be turned to any practical purpose, or that it possessed any physiological or therapeutic effects on the animal economy. Those who use the *cui bono* argument against philosophical investigations, on the ground that at first they may appear to yield no practical benefit, will find that argument fully refuted in this as in many other instances; for here we have a chemical compound which for many years after its discovery was merely interesting as a matter of scientific curiosity and research, becoming latterly an article of great importance and extensive manufacture, as a medicinal agent by which human

Chloroform.

suffering and agony may be annulled under some of the most trying circumstances in which human nature is ever placed.

Modes of preparation.

Chloroform may be obtained by various processes; as, 1, by passing a stream of chlorine gas into an alkaline solution of caustic potass; 2, by decomposing chloral with the agency of aqueous fixed alkalies; 3, by heating acetate of potass or acetate of soda with chloride of lime; 4, by boiling chloroacetic acid with aqueous ammonia; 5, by decomposing chloride of methyl by chlorine in a vessel exposed to the sun's rays; 6, by distilling alcohol, pyroxilic or wood spirit, or acetone with chloride of lime, &c. &c. Some vegetable oils, as those of turpentine, lemons, bergamot, peppermint, &c., when heated with chloride of lime and water, yield chloroform. When manufactured on a large scale, chloroform is prepared by distilling a mixture consisting of six parts of chloride of lime, or common bleaching powder, in thirty parts of water, and one part of alcohol. The fluid which passes over separates into two layers, the lower of which is chloroform; and the upper layer consists principally of a solution of weak spirit. The chloroform, before it can be safely used, requires, however, to be much purified. For, 1st, in order to remove the water and alcohol mixed with it, it is shaken up with about half its volume of strong sulphuric acid, slowly added; and, 2dly, to remove the acid, the chloroform is redistilled from milk of lime. Sometimes it is redistilled a third or even a fourth time, after being allowed to stand over quicklime, in order to render it completely pure, and of the requisite specific gravity. For other methods, and full details as to the manufacture of chloroform on the large scale, we need only refer to the pharmacopœias and dispensatories, and the various text-books on chemistry.

Physical and chemical properties.

It is a clear, colourless, limpid liquid; heavy, and of a specific gravity varying from 1·480 to 1·500; not inflammable; very volatile; it boils at 140° Fahr., and remains liquid and transparent at 4° Fahr. The density of its vapour is 4·13, or it is about four times heavier than atmospheric air. It has a fragrant, ethereal, fruit-like odour, and a slightly acrid, but at the same time intensely sweet, saccharine taste. It dissolves very sparingly in water, to which it imparts its sweet odour and taste; but it mixes in all proportions with alcohol. It is a powerful solvent, speedily dissolving camphor, gutta-percha, wax, resins, &c.

Impurities.

Chloroform is often found in the market very impure, and containing empyreumatic oils, aldehyde, chlorine, free muriatic acid, &c. When so contaminated, its medicinal use, by inhalation, is liable to be attended by headache, cough, nausea, &c. It deserves to be particularly known that the purest chloroform will sometimes spontaneously decompose if left exposed for a length of time to the combined influence of heat and light. Hence, when the liquid is kept for medical purposes, and particularly in warm climates, it is a matter of importance to keep it in a dark and cool place.

Physiological effects.

When inhaled in small quantities only, and slowly, the influence of chloroform upon the system is exhilarating and intoxicating, like the influence of alcohol or any diffusible stimulant.

When inhaled in larger and continuous doses, with the view of suspending pain in surgical, obstetrical, or medical practice, its effects are generally as follows:—After a few inhalations there supervenes a feeling of warmth and exhilaration, radiating from the heart towards the extremities, but generally perceived first in the extremities themselves. In most persons this feeling is speedily followed by a sensation of vibratory thrilling and benumbing throughout the body, and by affections of the organs of sense, as by loud whirring noises in the ears, or brilliant lights before the eyes. After one or two additional inhalations there is a rapid loss of sensation and voluntary motion, and at last a total suspension of consciousness. The state induced is a condition of deep artificial sleep. During this anæsthetic sleep, the relation between the mental condition of the patient and his unsusceptibility to the feeling of pain differs much in different individuals, and is greatly regulated by the amount of dose that is used. When the dose is at last full and complete, and such as is now usually given before most great surgical operations, no mental action appears to go on, or, at least, none whatever is remembered. In other persons, however, and especially when the dose is not so great and complete, though all consciousness of pain is suspended, the mind is still active as in dreams; and occasionally, though rarely, this peculiarity is observable—that the same type of dream recurs to the same individual every time he is subjected to the anæsthetic vapour. Sometimes when the dose of chloroform is not sufficiently great, a patient will wince or cry out under the use of the surgeon's knife or cautery, and afterwards on awaking declare that he has felt nothing. In such cases a certain amount of sensibility and consciousness appear to remain, but the memory of the patient subsequently retains no recollection whatever of any circumstances that have happened during his temporary anæsthetic sleep. Persons occasionally will talk ramblingly when subjected to an incomplete dose; but this rarely happens, except some of those around are conversing and exciting the patient; and it can be readily arrested by an additional dose of the anæsthetic, and by enforcing quietude. In other persons again, sometimes, when the dose is small, sensation is found to be suspended, and freedom from pain obtained, whilst still a greater or less amount of mental consciousness and intellectual activity and clearness remains. Their sensibility to suffering is more or less completely deadened, while their intelligence is preserved. The muscles of voluntary motion usually become more and more relaxed as the intensity of the anæsthetic effect increases, and at last their action can always be thoroughly suspended—a matter of great surgical moment in relation to the reduction of dislocations. But occasionally, before this total relaxation is produced, a state of spasm supervenes, particularly if the patient is held and restrained, or excited by talking and noises during the inhalation of the chloroform. Generally the pulse is increased in frequency during the first inhalations, but when the system is fully brought under the influence of the anæsthetic it decreases to its natural standard, or even becomes slower than natural; and few persons are able to bear with total impunity the wounds of a severe surgical operation until the anæsthetic vapour is given to such an extent as to have reduced the pulse to this degree. The respiration, though unaffected at first, becomes slower and deeper as the influence of the anæsthetic increases; and usually it is rendered soporose before any great surgical operation is begun. The temperature of the body decreases when the action of the chloroform is long continued.

The rapidity with which the effects of chloroform upon the mind and body disappear is perhaps not less wonderful than the rapidity with which they supervene. Generally the awakening from the anæsthetic sleep is in the course of a few minutes after the inhalation is arrested. When the patient is left undisturbed, he usually awakes to a state of perfect consciousness; but sometimes, particularly if roused artificially or too early, a few minutes will elapse before he is perfectly master of his own state and situation. When the drug used is pure no headache follows. In some cases there is left a tendency to sleep.

Therapeutic uses.

The inhalation of chloroform is now extensively employed by professional men to fulfil various purposes in the practices of surgery, midwifery, medicine, and medical jurisprudence.

In Surgery.

In surgery it is employed with different indications, as, 1. And principally, to annul and abolish the pain and agony attendant upon the various chirurgical operations, whether

Chloroform. these operations are performed with the knife, caustic, ligature, or otherwise. But the surgeon finds great value in its use in other matters of practice, as, 2. In enabling him to make a far clearer examination and more accurate diagnosis in some difficult cases of injury and disease, such as fractures, dislocations, stone, &c. 3. By the total relaxation which a full dose produces, the reduction of dislocations, herniæ, &c., is much simplified and facilitated. 4. The removal of patients who have suffered severe injuries or wounds, to their homes or to hospitals (a matter often attended with much and exhausting suffering), has now, by the previous use of chloroform, been often accomplished without pain and without danger. 5. The agony attendant upon the daily dressing of large wounds, as those made by burns, amputations, &c., has been abolished by its employment. 6. Under the use of chloroform amputations and other operations, required after severe injuries and wounds, are sometimes capable of being performed when, without it, the state of shock and depression would otherwise totally forbid operative interference. And lastly, the mortality accompanying surgical operations has been in a marked degree diminished and lessened since the general introduction of anæsthetics.

In Midwifery. Various important objects are gained by the accoucheur through the employment of chloroform in midwifery. 1. By its use he is enabled to save the mother from the suffering attendant upon the process of common parturition in the human female, and that without placing his patient in a degree of anæsthesia by any means so deep, and hence so dangerous, as is required in surgery. 2. In morbid or difficult cases of labour, requiring manual or instrumental interference, the state of anæsthesia enables him to apply that interference without pain to his patient, and generally with much greater facility to himself. 3. By its aid the process of obstetric diagnosis is, in many circumstances of doubt and difficulty, very greatly improved and facilitated. 4. By its relaxing effects it renders the dilatation of the maternal canals more easy, especially where these canals have any tendency to spasmodic rigidity and contraction. 5. In cases where arrestment of uterine action is a matter of great importance, as in the operation of version, &c., a very complete and very deep dose of chloroform enables us to attain this object far better and more speedily than by opium or other means. 6. Chloroform seems generally capable of reducing and keeping in abeyance one of the most common and most fatal complications in difficult labour, namely, puerperal convulsions. And, lastly, by saving the constitution of the patient from the pain attendant on the process of human parturition, it saves her strength and constitution, expedites her convalescence, and renders her proportionably less liable to the various affections which occur in the puerperal state.

In Medicine. The inhalation of chloroform has been employed in medicine for various purposes:—1. As an anodyne or anæsthetic in severe and exhausting pains, whether inflammatory or neuralgic; as in earache, toothache, pleurodyne, tic, &c. 2. As a narcotic in cases of delirium tremens, of puerperal and other forms of mania, and in other diseases where there is wakefulness and excitement. 3. As an antispasmodic in colic, dysmenorrhœa, laryngismus, asthma, hooping cough, the pains attendant on the passage of biliary and renal calculi, in chorea, tetanus, hysteria, and in infantile and other forms of convulsion. 4. In small doses as a diffusible stimulant to arrest the first commencement of the rigor in ague, in ephemeral fever, &c., and to support the excitement of the system where the stomach will not bear wine or other stimulants. Lastly, it has been used, particularly by some German and French physicians, in inflammatory affections alike of the head, chest, and abdomen. In the hospital of Frankfort and elsewhere small and frequently repeated inhalations of chloroform have been extensively employed in inflammation of the lungs, with the effect, it is alleged, of more marked relief to the cough pain, and fever, and a more speedy resolution of the disease than under any other treatment with which it was contrasted. It will probably ere long be applied to other uses in medicine.

Chloroform, administered by the stomach and not by the lungs, is also used by physicians. The usual dose of the drug when swallowed is from five to twenty drops, dissolved in a mucilaginous or oily liquid. In this form it exerts in a less marked but in a more prolonged degree the same therapeutical effects as the inhalation of the drug by the lungs.

In Legal medicine. In the detection of feigned diseases, as in pretended paralysis and contractions of limbs, in simulated deafness, &c., chloroform has been successfully used by army surgeons and others.

Other anæsthetic agents. Various chemical gases and vapours beside chloroform have been found when inhaled to possess the effect of producing, some in a more, others in a less marked degree, a state of anæsthetic insensibility and sleep. Among these we may enumerate protoxide of nitrogen (the "laughing gas" of Sir Humphry Davy), olefiant gas, light carburetted hydrogen, bisulphuret of carbon, chloride of hydrocarbon, or Dutch liquid, aldehyde, acetone, coal and rock naphtha, benzoine, and various ethers, as the nitric, acetic, hydrochloric, formic and other ethers, but particularly sulphuric ether.

It has also been supposed that the odour and vapours of some vegetable substances can exert an anæsthetic effect. We shall afterwards see that the ancients believed that the odour of mandragora, and that vapours arising from the concentrated juices of henbane, hemlock, &c., were capable of producing insensibility to surgical operations. Knowing the soporific effects of the common puff-ball (*Lycoperdon bovista*) upon the working bee, we some years ago made repeated trials of the effects of it, but without ever producing any very marked degree of anæsthesia in man. Since that time it has been tried by Mr Richardson and others, but, we believe, without any greater success.

Advantages of chloroform. The advantages which chloroform possesses over the other anæsthetic agents hitherto discovered are various. A smaller, and hence a more portable quantity of chloroform than of other anæsthetics is required in order to produce the state of anæsthesia; its action is more perfect and more certain; it exerts in ordinary doses no such depressing effects on the heart and general system as most of those chemical compounds which we have enumerated do; it acts rapidly, and consequently with a comparative short stage of excitement; its inhalation is infinitely more agreeable than the inhalation of most other anæsthetic gases or vapours; its odour is rapidly evanescent, and does not adhere to the clothes of those near it, giving it in this respect no small advantage with the busy physician over the persistent and disagreeable smell of sulphuric ether, &c.; it is cheaper than any other known anæsthetic; and, lastly, no special instrument requires to be used in its exhibition.

Dose, and mode of exhibition. To produce such a complete anæsthetic effect as is required for most surgical operations a larger and more rapid dose is necessary than in obstetric practice; whilst in midwifery the drug requires to be given in smaller quantities, but for a far greater stretch of time than in surgery. Numerous forms of instruments have been proposed for the exhibition of chloroform by inhalation, but they merely complicate the process; and certainly the simplest as well as the safest apparatus is a piece of sponge, or a towel or handkerchief.

In Surgery. Two or three fluid drachms of the liquid diffused upon the interior of a towel or pocket handkerchief, arranged in a somewhat concave form in the hand of the exhibitor, and applied over the mouth and nose of the patient, generally

Chloroform.

suffice to produce speedy and complete anæsthesia. If such an effect does not follow, an additional dose ought to be poured on the handkerchief at the end of a minute or two, for the drug rapidly evaporates. At first the moistened handkerchief ought to be held at the distance of half an inch or an inch from the face of the patient to allow free access of air to the mouth and nostrils, and afterwards it should be gradually approached nearer. At last it should touch the face except at one side where the fingers interpose between the face and it, to allow of a sufficient access of atmospheric air. In order that the patient may be brought speedily under the influence of the drug, and with as short an excited stage as possible, the vapour should be allowed to pass into the air tubes by both the mouth and nostrils, and all means of compressing either of these two cavities by the fingers or instruments must be strictly avoided. It should always be remembered that the vapour of chloroform is about four times heavier than atmospheric air, and hence the handkerchief or towel should be held in such a position over the mouth and nostrils, or so adjusted about the lower part of the face as to allow the vapour, by its mere gravitation, to fall into the air passages. Not unfrequently, at the moment when the patient is first becoming insensible, he will suddenly withdraw his face, or forcibly push aside the handkerchief with his hand; but the handkerchief should be instantly so reapplied as to allow the vapour to gravitate towards, and be drawn into the mouth and nostrils; and a few additional inhalations will now, after this point of excitement, render the patient quite insensible. The tests of the patient being fully anæsthetized that are usually most relied upon in practice, consist of induced slowness of the pulse, or some degree of noise or sopor in the respiration. Either or both of these phenomena, viz., slowness of the pulse, or some noise in the respiration, indicate that the patient is sufficiently insensible for undergoing any surgical operation, and the chloroform handkerchief must be withdrawn as soon as they supervene. Subsequently, only smaller and intermitting doses of the vapour are in general required in order to maintain an adequate state of anæsthesia during the performance of the operation. The principal error committed in using chloroform in surgery consists in giving it at first in such small doses, or so slowly, as to keep up a state of excitement instead of inducing a true state of anæsthesia; and a still more grievous error is sometimes committed in commencing the use of the knife before the pulse or respiration is affected, and consequently while the patient is not yet sufficiently anæsthetized.

Exhibition in Midwifery.

In midwifery practice there are two leading peculiarities in regard to the exhibition of chloroform, viz., first, that it is given to the patient only when the parturient actions or pains are present, and is always totally and entirely withdrawn in the intervals between these contractions or pains. The neglect of this simple but all-important rule has led, on the part of some practitioners, to much error and misconception regarding the effects and utility of chloroform in midwifery. But, secondly, the drug does not require to be given in such large and full doses in midwifery as in surgery, except where severe obstetric operations are to be performed. And, as ample experience has now shown, it may be given in common obstetric practice with perfect safety for two, four, six, or more hours, if the two simple rules alluded to above be duly followed.

In medical diseases.

When used in the treatment of medical diseases, chloroform is sometimes employed for a much longer time than in either midwifery or surgery. Patients suffering under tetanus, peritonitis, &c., have sometimes been kept more or less under its influence for two, three, or more continuous days. We have seen a child affected with infantile convulsions of such severity as to defy all other means, kept under the agency of chloroform with slight intermissions, to allow of food being taken, &c., for fourteen days, with the effect of arresting the fits, and ultimately saving the life of the little patient.

We have as yet found no human being capable of withstanding the anæsthetic effect of chloroform, though sometimes in exceptional cases a much larger dose is required than in others; and the actual amount necessary in any case can be judged of only by the actual effects of the drug, and not by any rules as to its mere measurement or quantity.

Contra-indications.

There are perhaps few morbid states which entirely contra-indicate the use of chloroform when required as an anæsthetic agent. It is generally, however, believed that marked disease of the valves of the heart, or fatty degeneration of the walls of that organ, and diseased states of the brain, form reasons for avoiding its employment. It should not be given in large doses—as for surgical operations—shortly after meals; otherwise sickness and vomiting of the contents of the stomach are liable to follow. A little previous fasting usually prevents this complication.

Cautions.

In the way of caution in the employment of chloroform, the points that demand the principal attention are the following:—1. The drug employed should be as pure as possible, and free from those various deleterious ingredients that are sometimes found mixed up with it, and which are liable to produce cough, headache, &c. 2. In its exhibition there ought always to be allowed to enter with the vapour of chloroform a free intermixture of atmospheric air, the fingers of the exhibitor being for this purpose always kept placed at one side between the face of the patient and the chloroformed towel or handkerchief; and, 3. Its action should always be suspended, and the handkerchief or instrument containing it instantly removed, whenever snoring and stertor supervenes in the respiration, or when the pulse becomes languid, and falls much below the natural standard; or when the face and lips greatly alter in their colour either to pallor or lividity.

Dangers.

The exhibition of chloroform, as of every other potent drug used in medicine, is liable to be attended with danger and death, provided it be given in too large or in too long continued doses. Like most other valued medicinal agents, it is powerful for evil as well as for good. But its occasional disagreement with, or deleterious influence upon one in 10,000 or 20,000 patients, is no sound argument against other patients benefiting from its employment. It has been calculated, from the returns of the registrar-general, that every year in England and Wales alone some 300 or 400 human beings are poisoned with opium; but certainly no one would argue that this is any reason why opium, the most valuable remedy in our pharmacopœia, should not be given to other human beings in proper doses and in proper cases. Patients have often sunk under the depressing effects of calomel, antimony, digitalis, &c.; but such accidents, while they teach us very strong lessons of caution, form no reason why these most useful drugs should be banished from the pharmacopœia. Many persons are annually drowned in bathing; but no reasonable man would argue from such unfortunate occurrences that this powerful means of maintaining and restoring health be therefore abandoned and forsaken. Deaths certainly ever and anon occur in patients subjected to the influence of chloroform, but assuredly only very rarely indeed when a pure drug and all proper precautions are used. Perhaps the exhibition of any other potent medicinal agent in the materia medica, exhibited in equally full doses to as many hundreds of thousands of patients as have now inhaled full doses of chloroform, would have been followed by more accidents and deaths than have been witnessed in the use of this anæsthetic agent. When we consider the immense extent to which chloroform has already been employed in all quarters of the world in medicine, in surgery, and in midwifery, the frequent great im-

Chloroform.

purity of the drug, and the little care which has sometimes been observed in its use, the wonder perhaps really is, that so few accidents have happened from its employment. And as a counter-balance to these accidents, we know from statistical evidence the fact, that in the absolute, it has been a great means, not only of saving human suffering, but also of saving human life, by diminishing in a marked ratio the danger and fatality attendant upon surgical operations and diseased states. Thus, let us take amputation of the thigh as an example. Out of 987 cases of this operation, collected by Mr Phillips, 435 proved fatal, or 44 in every 100 died. But out of 144 amputations of the thigh performed upon patients in an anæsthetic state, only 27 proved fatal, or 25 in 100 died. According to this computation the number of persons saved from death in amputation of the thigh by the patients being anæsthetized during the operation, amounts to 19 lives in every 100 operations performed, or to 190 lives out of every 1000 such operations.

All the patients that die under the hand of the operator when chloroform is used do not necessarily die from the effects of the chloroform upon the constitution. In several of the recorded cases, the dose given was far too small to have had any such fatal effect. Before the time that anæsthetics came to be used in surgery, deaths on the operation table ever and anon occurred. Such cases have been recorded by Brodie, Cooper, Home, Travers, &c. &c., but they excited no marked share of professional attention, as they were generally supposed to be accidents against which no caution could be of any use. Of late years, and since chloroform has been employed, they have usually been directly and at once ascribed to the deleterious action of the chloroform. The week after the anæsthetic effect of chloroform was discovered in Edinburgh, a patient suddenly died upon the operating table in the infirmary of that city, immediately after the first incisions for the reduction of a hernia were made, and before the operation was finished. Fortunately, from special casual circumstances, chloroform was not used in this case, or otherwise the drug would doubtlessly have been blamed for the result. We know of two other cases in the same city in which, since the introduction of chloroform, patients have died during or immediately after surgical operations, and in both of which, from accident rather than any other cause, chloroform did not happen to be used or to be at hand for use.

Treatment for overdose.

When in any case too powerful and large a dose of chloroform is given, the means of recovery which ought to be pursued are chiefly the following:—1. The instant removal of the chloroform handkerchief or instrument, and of everything containing the liquid, from the neighbourhood of the patient. 2. The supine position. 3. The free access of pure air to his face. 4. If necessary, the performance and continuance of artificial respiration by alternate compression and relaxation of the walls of the chest, or other means, taking special care at the same time to pull forward the tongue in the first instance, provided it has fallen backwards on the top of the windpipe. Some authorities have recommended the use of galvanism if an apparatus be at hand, the inhalation of oxygen or ammonia, inversion of the body, &c. No liquid should be poured into the mouth of the patient till he is able to swallow.

Local anæsthesia.

Instead of being inhaled so as to produce a constitutional anæsthetic effect, chloroform is sometimes used locally in the form of a liquid or vapour with the view of obtunding the sensibility of that individual part of the body only to which the agent is directly applied. The local application of chloroform alone, or mixed with oil, is one of the most powerful local sedatives which the materia medica possesses; and as such often relieves rheumatic, neuralgic, and other pains, when applied to the suffering part. But in the human subject, the degree of partial and superficial local anæsthesia which is capable of being produced by chloroform liquid or vapour is never sufficiently great to allow of the part being cut or operated upon without pain. All late experience has gone to prove the truth of this observation in regard to man. But in some of the lower animals complete local and limited anæsthesia can be readily induced by the local application of chloroform. For example—in the articulata, as in the common earthworm and the centipede, the application of chloroform to the head or tail of the animal or to individual medial rings will render the parts touched altogether anæsthetic, whilst the remainder of the body retains its natural state. Latterly, in the human subject, it has been proposed by Dr James Arnott to produce local anæsthesia, before some minor surgical operations, by previously freezing or frost-biting the affected part by the application of a strong frigorific mixture. In most people no inconsiderable amount of pain attends this process of sudden local freezing; the part frozen is not in a condition admitting of easy surgical interference with common instruments, and the state of anæsthesia does not extend beyond the skin and subcutaneary cellular tissue.

History of anæsthetics.

The vapour of chloroform was first proposed by Dr Simpson as an anæsthetic agent in surgery and midwifery in 1847. For a year previously, the vapour of sulphuric ether had been used to a considerable extent both in America and Europe, for the purpose of inducing insensibility to pain in surgical operations. It was first practically adopted for this purpose in 1846 by Dr Morton, a dentist at Boston in America. Subsequently Dr Charles T. Jackson of that city claimed the merit of having suggested to Dr Morton sulphuric ether as an agent capable of producing insensibility to pain. But the power of producing, by the vapour of sulphuric ether, an insensibility exactly like that produced by the inhalation of nitrous oxide gas, had been long previously known. The fact had been already often published by several American authorities, as by Godwin (1822), Mitchell (1832), Professor Samuel Jackson (1833), Wood and Bache (1834). Richard Pearson was the first to suggest the inhalation of suphuric ether in medicine in 1795; and he then described its employment in some cases of phthisis, asthma, hooping cough, &c. The sedative effects of its inhalation in these affections have been noticed by almost every author who has written at any length on the Materia Medica during the first half of the present century. In 1816 Nysten proposed and described a special instrument for the inhalation of sulphuric ether.

The idea, however, of saving by some artificial means the human body from the pains and tortures inflicted by the knife of the surgeon, is by no means a thought either first broached or first acted upon in recent times. For the production of anæsthesia a variety of measures had been suggested, and some used long before sulphuric ether and chloroform were applied to this purpose. In 1828 Dr Hickman appears to have proposed the inhalation of diluted carbonic acid gas as an agent capable of inducing insensibility in surgical operations; and the anæsthetic properties of carbonic acid have been long known and often witnessed in the experiments constantly performed before travellers on the dogs which are so often made to breathe this gas in the Grotto del Cane near Naples. In 1800 Sir Humphry Davy threw out a hint as to the possibility of applying nitrous oxide as an anæsthetic. In 1784 Dr Moore attempted to produce local anæsthesia in limbs requiring amputation or other operations, by previously compressing and obtunding the nerves of the implicated extremity—an idea, however, which was suggested long before Moore's time by Ambrose Parè. In the sixteenth and seventeenth centuries various authorities, as Valverdi, Hoffman, &c., suggested the possibility of producing temporary anæsthesia during surgical operations, by a plan sometimes successfully adopted by modern robbers, viz., by such an amount of "garotting" or compression of the vessels of the

neck as would produce the requisite amount of stupor and coma. Some surgeons also proposed to induce before operat'ng a state of fainting, and consequently of insensibility, by a previous profuse blood-letting, &c. The administration of a large opiate has been also repeatedly suggested and tried by various authorities; but the amount of dose required to produce true anæsthesia and insensibility to the pain of a surgical operation was found to be far too large to be free from imminent danger to the life of the patient.

Ancient anæsthetics.

But at a still earlier date different medicinal agents seem to have been suggested, and practically employed too, for the purpose of producing a state of anæsthesia during surgical operations. These agents were sometimes used in the form of odours or vapours, or by inhalation; and sometimes they were administered by the stomach. Two different drugs appear to have been more particularly used at different epochs with the view of inducing insensibility to the agony and torture otherwise following the surgeon's knife, viz., preparations, 1. of Indian hemp (*Cannabis sativa* var. *Indica*); and 2. of mandragora (*Atropa Mandragora*).

The anodyne, ecstatic, and anæsthetic effects of Indian hemp, and of the various preparations made from it, as bang, hachish, &c., have been long known in Africa and Asia. "The bang (as Sir Joseph Banks observed half a century ago) is prepared and, I believe, used in all parts of the East from Morocco to China. In Barbary (he adds) it is always taken, if it can be procured, by criminals condemned to suffer amputation; and it is said to enable those miserables to bear the rough operations of an unfeeling executioner, more than we Europeans can the keen knife of our most skilful surgeons." M. Julien lately pointed out to the French Academy an old Chinese work proving that 1500 years ago a preparation of hemp or ma-yo was employed medicinally in China to annul the pain attendant upon cauterization and surgical operations. The wonderful power of endurance of the Hindu Suttee appears to have been sometimes procured by the influence of this powerful drug. Some high biblical commentaries maintain that the gall and vinegar or myrrhed wine offered to our Saviour immediately before his crucifixion was a preparation, in all probability, of hemp, which was in these, as well as in later times, occasionally given to criminals before punishment or execution—while 700 years previously it is possibly spoken of, according to the same authorities, by the prophet Amos as the "wine of the condemned."

The symptoms described by Homer as produced on Ulysses and his companions by their drinking of the Egyptian nepenthes are far more like the effects of hemp than of any other known agent. Herodotus twice mentions the ecstatic influence which the inhalation of the vapour of burning hemp produces upon the Scythians and Massagetans, who, according to his account, breathed it for the purposes of excitement and inebriation.

The other plant mentioned—the mandragora—is now banished from the materia medica, but its therapeutic virtues certainly seem to call for some renewed investigation. Most of the old Greek and Roman physicians and writers, such as Galen, Aretæus, Celsus, &c., ascribe to it strong soporific powers; and several of them, but especially Dioscorides, Pliny, and Apuleius, describe its decoction or tincture as endowed with such anæsthetic powers that those drinking a proper dose of it are insensible to the pains of the surgeon's knife and cautery. It is given (writes Dioscorides eighteen centuries ago) "to cause insensibility (ποιεῖν ἀναισθησίαν), in those who are to be cut or cauterized; for being thrown into a deep sleep they do not perceive pain." The observations of Pliny, Apuleius, &c., are to the same effect. In the twelfth and thirteenth centuries Hugo of Lucca used, and his pupil Theodoric (who died in 1298) has described a somniferous ball or sponge, "Spongia somnifera," the vapours raised from which were capable, when inhaled, of setting patients into an anæsthetic sleep during surgical operations. This somniferous ball was, in the first instance, made by filling and imbibing a sponge with dried extracts of mandragora, opium, and other sedatives; and when required for use the sponge was dipped for a time in hot water, and the patient made to breathe the vapour thus raised from it till an anæsthetic sleep was produced. A modern French surgeon, M. Dauriol, states that he has successfully induced a state of anæsthesia in various surgical patients by the means described 600 years ago by Theodoric. Why the mandragora fell into disuse as an anæsthetic agent in surgery does not appear in any professional records. Aretæus, after speaking of the deep and long-continued sopor produced by drinking an infusion of mandragora, adds, that occasionally danger results from using it, and the patient may die convulsed. The frequency and the fear of such results may probably have been the cause of its anæsthetic employment in surgery falling into abeyance. Chamappe, a French surgeon who wrote in 1538, tells us that at that time "some surgeons give, like Theodoric, soporiferous medicines to their patients that they may not feel the incisions of the scalpel;" and he describes the "somniferous sponge" of Hugo as adapted for this purpose. But already towards the end of the same century, Ambrose Parè, the celebrated Parisian surgeon, alludes to the exhibition of mandragora "to avert the pain attendant upon the amputation of a limb" as a practice only used "formerly" by operators, and apparently as not followed in his own day. An early English author, Bulleyn (1579) describes the possibility of setting patients into an anæsthetic state during lithotomy, &c., by the use of mandragora; but at the same time he speaks of the sleep thus artificially produced as "a trance or a deepe terrible dreame."

The older authors do not always give explicit accounts of the substances and preparations which they recommend for use as anæsthetic agents. Occasionally, they affect an air of secrecy and mystery with regard to their composition and character. Thus, in the 8th book of his Natural Magic (1608), Baptista Porta gives various receipts for medicines which produce sleep, insanity, &c. Amongst others, he describes a "sleeping apple" (*Pomum somnificum*), made with mandragora, opium, &c., and the smelling of which binds, he avers, the eyes with a deep sleep. Subsequently, he states, that there can be extracted from soporific plants "a quintessence which must be kept in leaden vessels, very closely stopped, that it may not have the least vent, lest it fly out. When (he continues) you would use it, uncover it, and hold it to a sleeping man's nostrils, whose breath will suck up this subtle essence, which will so besiege the castle of his senses that he will be overwhelmed with a most profound sleep, not to be shook off without much labour. After sleep, no heaviness will remain in his head, nor any suspicion of art. These things (Porta adds) are manifest to a wise physician; to a wicked one, obscure." Meissner relates, at considerable detail, that towards the close of the seventeenth century, a secret remedy was exhibited by Weiss to Augustus II. of Poland, while his majesty was asleep, and during the state of anæsthesia thus induced the king's diseased foot was amputated. The operation was done without the royal patient's consent, and its performance was not discovered by him till the following morning.

The former general belief in the idea that a degree of anæsthetic and prolonged sleep could be induced artificially by certain medicated potions and preparations, is shown by the frequency with which the circumstance is alluded to by our own older poets and story-tellers, and made part of the machinery in the popular romance and drama. In the history of Taliesin (one of the antique Welsh tales, contained in the Mabinogion), Rhun is described as having set the maid of the wife of Elphin into a deep sleep with a powder put into her drink, and as having then cut off one of her

fingers when she was in this state of artificial anæsthesia. Shakspeare, besides alluding more than once to the soporific property of mandragora, describes with graphic power in Romeo and Juliet, and in Cymbeline, the imagined effects of subtle distilled potions, supposed capable of inducing, without danger, a prolonged state of death-like sleep or lethargy. And Middleton, in his tragedy of "Women, beware Women," published in 1657, pointedly and directly alludes, in the following lines, to the practice of anæsthesia in ancient surgery:—

> "I'll imitate the pities of old surgeons
> To this lost limb—who, ere they show their art,
> Cast one asleep, then cut the diseased part."

Indeed, the whole past history of anæsthetics is interesting as a remarkable illustration of the acknowledged fact that science has sometimes for a long season altogether lost sight of great practical thoughts, from being unprovided with proper means and instruments for carrying out these thoughts into practical execution; and hence, it ever and anon occurs that a supposed modern discovery is only the rediscovery of a principle already sufficiently known to other ages or other remote nations of men. (J. Y. S.)

CHLOROSIS (χλωρός, pale green), green-sickness—a disease of females, which is characterized by a peculiar sallowness of the complexion, debility, dyspepsia, &c. The best remedies are tonics, exercise in the open air, cold bathing, and similar means calculated to restore vigour to the constitution.

CHOCOLATE, a nutritive preparation of the kernels of the cacao nut, usually sweetened with sugar, and aromatized with vanilla, cinnamon, or cloves. It is prepared by triturating in a heated mortar the roasted kernels, which thus, from the oil they contain, assume a pasty consistence; and this paste is then shaped into cakes or sticks in moulds of tin. If necessary, water may be added during the process of trituration. It is either eaten solid, or dissolved in boiling water or milk. Cacao, under its native name of *chocolate*, had been used for ages as a beverage among the Mexicans previous to the conquest of their country by the Spaniards in 1520; and had long been known in some of the West India Islands before it reached France in 1661, and whence, a few years later, it was introduced into Britain.

CHOCTAW INDIANS. See AMERICA, vol. ii. p. 680.

CHODOWIECKI, DANIEL, a celebrated engraver and painter, was born at Dantzic in 1726, and settled at Berlin. His spirited etchings, chiefly executed for books, are very numerous. Among his best works is the engraving of the unfortunate family of Calas. (See CALAS.) Chodowiecki was appointed director of the Royal Academy at Berlin, and died in 1801.

CHŒNIX, in *Antiquity*, a Greek measure of capacity, apparently of several sizes, varying from about 1½ to nearly 4 pints English.

CHOERINÆ, in *Antiquity*, small sea-shells used by the Athenian dicasts in voting.

CHOERILUS, an Athenian tragic poet, who flourished B.C. 500, and was contemporary with Thespis and Æschylus. He gained the tragic prize 13 times, but all his works have perished.

CHOERILUS of Samos, about B.C. 480–400, an epic poet. who wrote on the wars of the Greeks with the Persians. He is said to have been intimate with Herodotus, and he died at the Court of Archelaus.

CHOEROPOTAMUS, a fossil genus of *pachyderm*, allied to the *Peccary*, but of larger size. It was discovered by Cuvier in the gypsum of the Paris basin.

CHOIR (χορος, Lat. *chorus*), that part of a church or cathedral where choristers sing divine service. It is separated from the chancel, and also from the nave. The choir was separated from the nave in the time of Constantine, and in the twelfth century it was inclosed with walls; but the ancient balustrades have been since restored. The choir in nunneries is a large hall separated by a grate from the body of the church, where the nuns chant the service. Choir is also used to denote a band of singers in any church.

CHOISY-SUR-SEINE, or *Choisy le Roi*, a town of France, on the left bank of the Seine, 6 miles S.E. of Paris. Pop. 4000. It is a pleasantly situated and thriving manufacturing town, producing glass and china wares, morocco leather, soap, and chemicals.

CHOLERA, usually supposed to be derived from the two Greek words χολή and ῥέω, bile flux, but more probably from the Greek word χόλερα, a rain-gutter, when the affix of the word *morbus* showed it was the disease which was spoken of, and not the channel for water. Two principal forms of this disease occur: the first, the ordinary bilious or autumnal cholera; the other, the epidemic, malignant, or Asiatic cholera. In the bilious cholera, which prevails to a greater or less extent every autumn, violent vomiting and purging occur, but the discharges contain a large quantity of bilious matter. There is much pain in the stomach and bowels, with more or less spasm of the muscles of the abdomen and extremities, with great prostration of strength, &c. In epidemic or malignant cholera, after the contents of the stomach and bowels are evacuated, the discharges consist of a nearly colourless fluid, filled with flocculi, and resemble water in which rice has been boiled. No bile nor urine is secreted; the whole surface of the body is cold, shrunk, collapsed, with a leaden cadaverous hue, and severe spasms both of the muscles of the abdomen and of the extremities. This stage of collapse and prostration sometimes occurs quite suddenly, but usually is preceded by ordinary diarrhœa, or bowel complaint, of some hours or days continuance. When the person rallies from the stage of collapse, he usually passes through a febrile stage before returning to health, as if the cholera were but a plague variety of epidemic typhus fever.

Malignant cholera has been long known in India; but it is commonly stated that it has only been of late years that it has extended its ravages over the rest of the world. Like all epidemic plagues, it has in its course followed the great leading tracks of commerce or of the march of armies, stealing slowly but surely along the banks of rivers, the great roads, and the lines of traffic, and attacking in succession city after city. No barriers, natural or artificial, nor military cordons have been able to arrest its progress in the slightest degree. It has crossed rivers, mountains, seas, and deserts, always falling most heavily on the inhabitants of those towns, hamlets, or houses where deficient drainage and ventilation, accumulations of putrescent matters, want of personal cleanliness, and intemperance, were most prevalent. In the European cities it has selected as its especial site all the usual haunts of typhus fever, and has attacked the inhabitants of almost every locality where typhus fever was known to prevail and be endemic. It has ever shown itself most fatal in the neighbourhood of rivers and marshes; and the able report of Mr Farr on the cholera in England clearly demonstrates that in London the mortality from cholera bore an exact arithmetical ratio to the height of the districts above the level of the Thames: the higher above the level of the Thames the less was the mortality from the disease.

When this virulent disease attacks an army or a town, the most effectual remedy seems to be to leave the ground or town immediately, and scatter the people over the face of the country. Even in crowded cities it has been found that by removing the inhabitants from the localities where it breaks out, and locating them in airy and well ventilated and well drained situations, they remain free from the disease, which they could not do were the disease contagious in the proper sense of the word.

As to treatment, when the disease prevails epidemically, the very first symptoms of diarrhœa must be watched and treated instantly by the usual remedies, as chalk mixture, or with tincture of catechu and opium. When the disease passes to the stage of collapse, it is remarkable that, whether treated or not, just about a half recover; and as the disease abates, this proportion increases to two-thirds. The treatment by salines, that is repeated drinks of carbonate of soda and tartaric or citric acid, and also the administration of diluted sulphuric acid, 20 to 40 drops every half-hour, have been highly praised as the remedies most likely to conduct the patient through the disease; and where a fair trial has been made of these remedies, they happen to have answered the purpose better than any others. (J. S-K.)

CHOLET, a town of France, department of Maine-et-Loire, arrondissement and 12 miles S.S.E. of Beaupréau. Pop. 7539. It has extensive manufactures of woollen, linen, and cotton goods, with bleachfields, dyeworks, &c.

CHOPIN (French, *chopine*), a liquid measure in Scotland and France, equal to half a Scotch pint.

CHORAGIC, pertaining to the ancient chorus. Hence *choragic monument* signifies a monument erected in honour of the choragus who gained the prize for the exhibition of the best theatrical or musical entertainment at the festival of Bacchus. The remains of two very fine monuments of this kind still exist at Athens.

CHORAGUS, in *Antiquity*, an officer at Athens who presided over the chorus in the theatre and at religious solemnities, and defrayed the greater part of the expenses.

CHORASSAN, or KHORASSAN. See KHORASSAN.

CHORD, or CORD (Latin *chorda*, Greek χορδή, an intestine, of which strings were made), primarily denotes a slender rope or string. When used to denote the string of a musical instrument it is generally written *chord*; and when applied to an ordinary string or small rope it is written *cord*.

CHORD, in *Geometry*, a right line drawn from one end of an arc of a circle to the other.

Chord, in *Music*. See MUSIC.

CHOREA (χορός, a chorus—the ancient accompaniment to dancing), the medical name for the disease commonly called St Vitus's Dance.

CHOREGRAPHY (χορεία, dancing, γράφω, to describe), the art of representing by signs the various motions and gestures in dancing, as music is represented by notes.

CHORIAMBUS, in ancient poetry, a foot consisting of four syllables, of which the first and fourth are long, and the second and third short; or a foot consisting of a trochæus and iambus.

CHORLEY, a market-town of Lancashire, 28 miles S.S.E. of Lancaster, and 210 miles from London by the North-Western railway. It stands on the Chor, and on the Liverpool and Leeds canal. Pop. (1851) 8907. The town is well built, and abundantly supplied with water from a reservoir into which the stream is thrown up by steam machinery. It has an ancient parish church in the Norman style, a handsome Gothic church, a Roman Catholic and other chapels, grammar-school, town-hall, &c. There are also numerous mills for the manufacture of cotton yarn, muslins, jaconets, and fancy goods; with bleachfields, print-works, &c. In the vicinity are coal, lead, and iron mines, and slate and stone quarries.

CHORUS, in the ancient drama. See DRAMA.

CHORUS, in *Music*, a composition of two, three, four, or more parts, each of which is intended to be sung by a plurality of voices. Choruses are made to follow a piece of music sung by one individual, or in parts by single or at least only a few voices, and, as it were, bring to a climax the joy, adoration, grief, or any other sentiment or passion therein expressed. The choruses of Handel, particularly those in his oratorio of the "Messiah," are considered as the finest compositions of the kind, and, when well performed with complete orchestral accompaniments, produce the most triumphant effect of which music is capable. Chorus is also applied to those who sing the parts.

CHOTYN or CHOCZIM, a strongly fortified town of European Russia, province of Bessarabia, situated on a hill on the right bank of the Dniester, 16 miles S.W. of Kamenetz. Pop. 8000. In 1739 the Russians here defeated the Turks and took possession of the town; which was subsequently restored to the Turks in 1769. It again fell into the hand of the Russians, and was once more restored by the peace of Kainardgi in 1774. The united armies of the Russians and Austrians, after a siege, compelled it to surrender in 1788; but it reverted to the Turks at the peace of Jassy in 1792. It was finally ceded by Turkey to Russia, along with Bessarabia and part of Moldavia, in 1812.

CHOUGH (pronounced *chuff*), a fowl of the genus Corvus. The Cornish chough is nearly of the size of the crow, which it resembles in plumage; but its bill, legs, and feet, are red. The jackdaw also is sometimes called by this name.

CHOUS (χοεύς, χοῦς), in *Antiquity*, a Greek liquid measure, equal to the Roman *congius*, and containing six sextarii, or nearly six pints English. Suidas mentions a smaller measure under the name of χοῦς, equal to only two sextarii. Chous is supposed to have been originally the common name for a drinking cup.

CHRISM (χρῖσμα, from χρίω *to anoint*), in the Roman and Greek Churches, oil consecrated by the bishop, and used in the administration of baptism, confirmation, ordination, and extreme unction. It is prepared on Holy Thursday with much ceremony. That used in ordination is more usually styled *unction*. *CHRISM Pence*, *CHRISMATIS Denarii*, or *CHRISMALES Denarii*, was a tribute anciently paid to the bishop by the parish clergy, for their chrism.

CHRIST (χριστός, *anointed*), THE ANOINTED—an appellation given to the Saviour of the world, and synonymous with the Hebrew MESSIAH. (See JESUS.) It was a custom of antiquity to consecrate persons to the prophetical, sacerdotal, and regal offices by anointing them with oil. This custom is preserved even to modern times, at the consecration of sovereigns and ecclesiastics.

Order of CHRIST, a military order, founded by Dionysius I. Portugal. They had their residence at first at Castromarin, but afterwards removed to the city of Thomar, as being nearer to the Moors of Andalucia and Estremadura.

Another military order of this name was instituted in 1205, by Albert, bishop of Riga, with the object of defending the new Christian converts of Livonia, who were persecuted by the Pagans. On their cloaks were represented a sword and a cross, and hence they were also denominated Brothers of the Sword.

CHRISTCHURCH, a parliamentary borough and market-town of Hampshire, England, situated at the confluence of the Avon and Stour, about half a mile from where their united streams fall into Christchurch bay, 20 miles S.W. of Southampton, and 100 miles from London. The town takes its name from its church and priory, founded early in the Saxon era. Some fragments of the priory walls are still standing; and the church, which is in the form of a cross, is a very interesting specimen of the Norman style, with a square tower at its west end commanding an extensive prospect. It also contains some curious ancient monuments. Christchurch had returned two members to parliament from the time of Elizabeth; but, by the Reform act, the number was reduced to one. Pop. (1851) of parliamentary borough 7475; of old borough 1877. Electors (1851–2) 313. It has some manufactures of watch-springs and hosiery, and a salmon fishery. On account of a shifting bar, where there is a depth of not more than five or six feet, the harbour is accessible only at spring tides to small coasting vessels. There is a double tide in the bay every 12 hours. In the vicinity

Christiania ‖ Christianity.

there are remains of a camp, with several tumuli and barrows.

CHRISTIANIA, the capital of Norway, province of Aggerhuus, stands at the northern extremity of the Christiania fiord, on the Agger, in N. Lat. 59. 55. E. Long. 10. 49. Pop. (1845) 26,141. The city is built on an agreeable slope facing the south, and graduating into the country by means of innumerable villas intermingled with wood, and usually built in commanding situations. The entire aspect of the town and surrounding scenery is exceedingly pleasing and peculiar. The town is regularly laid out, the streets wide and straight, crossing each other at right angles, and the houses are all built of brick or stone, though few of them have any pretensions to architectural beauty. The castle of Aggerhuus, containing the regalia and national records, is picturesquely situated on a bold promontory at its southern extremity, commanding at once the fiord and the greater part of the town. The ramparts are laid out in walks, and form an agreeable promenade. The principal public buildings are the new palace, the Storthing or legislative hall, cathedral, theatre, free-masons' hall, &c. The university, founded in 1811, is attended by about 800 students, and has a library of 130,000 volumes, excellent museums, astronomical and magnetical observatories, and a botanic garden. There are also a military academy and other schools, a military hospital, a lunatic and two orphan asylums, town-hall, exchange, a bank, and various literary and scientific societies. It has manufactures of woollen goods, tobacco, hardware, leather, paper, and soap, &c.; several distilleries and breweries; and an extensive trade in timber, fish, and other northern produce. The town has four suburbs, in which the houses are mostly of wood, these not being prohibited there as in the town. Christiania takes its name from Christian IV., by whom the city was founded close upon the site of the ancient city of Opslo, which, with the exception of the episcopal palace and a few houses, was entirely destroyed by fire in 1624. Opslo was founded in 1058 by King Harald Haardraade, and rose to be the third city of the kingdom. Upon the union of Norway with Denmark it became the capital of the former.

CHRISTIANITY.

Origin of the word.

CHRISTIANITY, the religion of Jesus Christ. The word is analogically derived, as other abstracts from their concretes, from the adjective *Christian*, which again is formed from the name Χριστός, *Christus*, the Anointed.

For the evidences and doctrines of Christianity see THEOLOGY.

For the general characteristics, early establishment, and corruptions of Christianity, see the third PRELIMINARY DISSERTATION.

Progress of Christianity.

The history of the world presents no phenomenon so remarkable as the rise and early progress of Christianity. Originating in a country not remarkable for any political, commercial, or literary influence; emanating from one who occupied an humble sphere in the community amidst which he appeared; and announced, in the first instance, by men of mean extraction, of no literary culture, and not endowed with any surpassing gifts of intellect; it nevertheless spread so rapidly that in an incredibly short period of time it had been diffused throughout the whole of the civilized world, and in the fourth century of its existence became the recognised and established religion of the Roman empire. When it is remembered that this result was achieved not only without the aid of any worldly influence, but in the face of the keenest opposition on the part of all the learning, wealth, wit, and power of the most enlightened and the mightiest nations of the earth, the conclusion is strongly forced upon us that a power beyond that of man was concerned in its success, and that its early and unexampled triumphs afford an incontestable proof of its inherent truth and its divine origin.

Mr Gibbon's reasoning.

To avoid this conclusion, deists have laboured to show that there were certain causes of a purely human kind which operated to the production of this result, and are sufficient to account for it. Of these attempts the most famous is that of Gibbon, who, in the fifteenth chapter of his great work, has discussed at length the causes of the growth of Christianity. He specifies five secondary causes, as he terms them, to which he insinuates the whole success of Christianity may be traced; and though he does not formally deny the divine origin of that religion, he leaves this altogether out of view, and plainly suggests that such a belief is in no degree necessitated by the facts of the case. The notoriety which his attack upon Christianity in this chapter has acquired renders it desirable that we should examine the causes which he has assigned as sufficient to account for the early success of the gospel.

The causes.

The secondary causes to which he ascribes these effects are, first, the inflexible and intolerant zeal of the Christians, derived from the Jewish religion, but purified from the narrow and unsocial spirit, which, instead of inviting, deterred the Gentiles from embracing the law of Moses; secondly, the doctrine of a future life, improved by every additional circumstance which could give weight and efficacy to that important truth; thirdly, the miraculous powers ascribed to the primitive church; fourthly, the pure and austere morals of the Christians; and, fifthly, the union and discipline of the Christian republic, which gradually formed an independent and increasing state in the heart of the Roman empire.

But before entering upon the examination of Mr Gibbon's causes in the order in which they are here enumerated, we beg leave to remark, that we cannot perceive the propriety of denominating some of these *secondary* causes, since the miraculous powers ascribed to the primitive church, if they were real, must have constituted a primary cause, and if fallacious, could have been no cause at all, except of its complete subversion. As little can we conceive how such an able and learned author could imagine a zeal strictly and properly inflexible and intolerant, as qualified to produce any other effect than the destruction of the system which they are allowed to have been anxious to promote. But our estimate of the causes assigned by Mr Gibbon will be more fully developed as we proceed in our first examination of them.

First cause.

In pointing out the connection between the first of these causes, and the effects which he represents as arising from it, this learned and ingenious writer observes, that the religion of the Jews does not seem to have been intended to be propagated among the heathens; and that the conversion of proselytes was rather accidental than consistent with the general spirit of the institutions of Judaism. The Jews were, of consequence, studious to preserve themselves as a peculiar people. Their zeal for their own religion was intolerant, narrow, and unsocial. In Christianity, when it made its appearance in the world, all the better part of the predominant spirit of Judaism was retained; but whatever might have a tendency to confine its influence within narrow limits was laid aside. Christians were to maintain the doctrines and adhere to the constitutions of their religion with sacred fidelity. They were not to violate their allegiance to Jesus by entertain-

ing or professing any reverence for Jupiter or any other of the heathen deities; it was not even necessary for them to comply with the positive and ceremonial institutions of the law of Moses, although these were acknowledged to have been of divine origin. The zeal, therefore, which their religion inculcated, was inflexible. It was even intolerant: for they were not to content themselves with professing Christianity and conforming to its laws; they were to labour with unremitting assiduity, and to expose themselves to every difficulty and every danger, in converting others to the same faith. But the same circumstances which rendered it thus intolerant, communicated to it a more liberal and a less unsocial spirit than that of Judaism. The religion of the Jews was intended only for the few tribes; Christianity was intended to become a catholic religion—its advantages were to be offered to all mankind. All the different sects which arose among the primitive Christians uniformly maintained the same zeal for the propagation of their own religion, and the same abhorrence for every other. The orthodox, the Ebionites, the Gnostics, and other sects, were all equally animated with the same exclusive zeal, and the same abhorrence of idolatry, which had distinguished the Jews from other nations.

Such is the general purport of what Mr Gibbon advances concerning the influence of the first of these secondary causes in the propagation of Christianity. It would be uncandid to deny, that his statement of facts appears, in this instance, to be almost fair, and his deductions tolerably logical. The first Christians were remarkable for their detestation of idolatry, and for the generous and disinterested zeal with which they laboured to convert others to the same faith. The first of these principles, no doubt, contributed to maintain the dignity and purity of Christianity; and the second to disseminate it throughout the world. But the facts which he relates are scarcely consistent throughout. He seems to represent the zeal of the first Christians as so hot and intolerant, that they could have no social intercourse with those who still adhered to the worship of heathen deities. But if so, how could they propagate their religion? Nay, we may even ask, how could they live? If they could not mingle with the heathens in the transactions either of peace or war; or witness the marriage or the funeral of the dearest friend, if a heathen; or practise the elegant arts of music, painting, eloquence, or poetry; or venture to use freely in conversation the language of Greece or of Rome; it is not easy to see what opportunities they could have had of disseminating their religious sentiments. If, in such circumstances, and observing rigidly such a tenor of conduct, they were yet able to propagate their religion with such amazing success as they are said to have done, they must surely either have practised some wonderful arts unknown to us, or have been assisted by the supernatural operation of divine power. But all the historical records of that period, whether sacred or profane, concur in proving that the primitive Christians in general did not retire with such religious horror from all intercourse with the heathens. They refused not to serve in the armies of the Roman empire. They appealed to heathen magistrates, and submitted respectfully to their decisions. The husband was often a heathen, and the wife a Christian; or, conversely, the husband a Christian, and the wife a heathen. These are facts so universally known and admitted, that we need not quote authorities in proof of them.

This distinguished writer appears, therefore, not to have stated the facts which he produces under this head with sufficient precision, nor to have reasoned from them correctly. Had the zeal of the first Christians been as intolerant as he represents it, it must have been highly unfavourable to the propagation of their religion; all their wishes to make converts would, in that case, have been counteracted by their unwillingness to mix, in the ordinary intercourse of life, with those who were to be converted. Their zeal, and the liberal spirit of their religion, were indeed secondary causes which contributed to its propagation; but their zeal was by no means so ridiculously intolerant as this writer would have us believe; for if it had, it must have produced effects directly opposite to those which he ascribes to it.

Second cause.

In illustrating the influence of the next of these secondary causes to which he ascribes the propagation of Christianity, Mr Gibbon displays no less ingenuity than in tracing the nature and the effects of the first. The doctrine of a future life, improved by every additional circumstance which can give weight and efficacy to that important truth, makes a conspicuous figure in the Christian system; and it is a doctrine highly flattering to the natural hopes and wishes of the human heart.

Though the heathen philosophers were not unacquainted with this doctrine, yet to them the spirituality of the human soul, its capacity of existence in a separate state from the body, its immortality, and its prospect of lasting happiness in a future life, rather appeared things possible and desirable, than truths fully established upon solid grounds. These doctrines, Mr Gibbon would persuade us, had no influence on the moral sentiments and general conduct of the heathens. Even the philosophers who amused themselves with displaying their eloquence and ingenuity on these splendid themes, did not allow them to influence the tenor of their lives; while the great body of the people, who were occupied in pursuits very different from the speculations of philosophy, and were unacquainted with the questions discussed in the schools, were scarcely ever at pains to reflect whether they consisted of a material and a spiritual part, or whether their existence was to be prolonged beyond the term of the present life; and they could not regulate their lives by principles which they did not know.

In the popular superstitions of the Greeks and Romans, the doctrine of a future state was not omitted. Mankind were not only flattered with the hopes of continuing to exist beyond the term of the present life, but different conditions of existence were promised or threatened, in which retributions for their conduct in life were to be enjoyed or suffered. Some were exalted to heaven, and associated with the gods; others were rewarded with less illustrious honours, and a more moderate state of happiness, in Elysium; while those who by their conduct in life had merited, not rewards, but punishments, were consigned to Tartarus. Such were the ideas of a future state which formed part of the popular superstitions of the Greeks and Romans. But these notions produced only a very faint impression on the minds of those among whom they prevailed. They were not truths supported by evidence; they were not even plausible; they were in fact a tissue of absurdities; they had not therefore a greater influence on the morals, than the more refined speculations of the philosophers. Even the Jews, whose religion and legislation were communicated from heaven, were in general, till within a very short period before the propagation of the gospel, as imperfectly acquainted with the doctrine of a future state as the Greeks and Romans. This doctrine formed no distinct part of the law of Moses, and it is but darkly intimated in the other parts of the Old Testament.

The rude tribes who inhabited ancient Gaul, and some other nations not more civilized than these, entertained ideas of a future life much clearer than those of the Greeks, the Romans, or even the Jews.

Christianity, however, explained and inculcated the

truth of this doctrine in all its splendour and all its dignity. It exhibited an alluring, yet not absurd, view of the happiness of a future life. It conferred new horrors on the place of punishment, and added new severity to the tortures to be inflicted, in another world. The authority on which it taught these doctrines, and displayed these views, was such as to silence doubt, and to command implicit belief. What added to the influence of the doctrine of a future state of existence, thus explained and inculcated, was, that the first Christians confidently prophesied and sincerely believed that the end of the world, the consummation of all things, was fast approaching, and that the generation then present would live to witness that awful event. Another circumstance which contributed to render this doctrine favourable to the propagation of Christianity was, that the first Christians dealt damnation without remorse, and almost without making any exceptions, on all who died in the belief of the absurdities of heathen superstition. Thus taught, and enforced with these additional and heightening circumstances, this doctrine, partly by presenting alluring prospects and exciting pleasing hopes, partly by working upon the fears of the human heart with representations of terror, operated in the most powerful manner in extending the influence of the Christian faith.

Here, however, facts are rather exaggerated, and the inferences unfairly deduced. It must be admitted that the speculations of the heathen philosophers did not fully and undeniably establish the doctrine of the immortality of the human soul; and hence their arguments could scarcely impress such a conviction of this truth as would influence in a very strong degree the moral sentiments and conduct. These arguments, however, were of such a kind that they must have produced some, nay a considerable influence. Several of the most illustrious among the heathen philosophers appear to have been so impressed with the belief of the soul's immortality, and of a future state of retribution, that their general conduct was constantly and in a high degree influenced by that belief. Socrates and Plato are eminent and well-known instances. And if, in such instances as these, the belief of the truths in question produced such effects, it may be fairly inferred, though we had no further evidence, that those characters were not singular in this respect. It is a truth acknowledged as unquestionable in the history of arts and sciences, that wherever any one person has cultivated these with extraordinary success, some of his contemporaries will always be found to rival his excellence, and a number of them will engage in the same pursuits. On this occasion we may venture, without hesitation, to reason upon the same principles. When the belief of the immortality of the human soul produced such illustrious patterns of virtue as a Socrates and a Plato, it must certainly have influenced the moral sentiments and conduct of many others, although in an inferior degree. Some who profess to believe the doctrines of Christianity, make this profession, even although they have never considered seriously whether they be true or false. But notwithstanding this, these truths still exert a powerful influence on the sentiments and manners of society in general. Thus, also, it appears that the doctrines of the ancient philosophy concerning a future life, and even the notions concerning Olympus, Elysium, and Tartarus, which formed part of the popular superstitions, produced a certain influence on the sentiments and manners of the heathens in general. That influence was often indeed inconsiderable, and not always beneficent; but still it seems to have been greater than Mr Gibbon is willing to allow. Christians have been sometimes at pains to exaggerate the absurdities of Pagan superstition, in order that the advantages of Christianity might acquire new value from the contrast. But here we find one who is at heart inimical to Christianity, displaying, and even exaggerating, these absurdities for a different purpose. The truth, however, may be safely admitted; and it is only when exaggerated that it can serve any purpose adverse to the authority of our holy religion. Mr Gibbon certainly represents the religious belief of the ancient Gauls, in respect to the immortality of the human soul and a future state, in too favourable a light. It is only because the system of superstition which prevailed among the barbarians is so imperfectly known, that it has been imagined to consist of more sublime doctrines than those of the popular superstitions of the Greeks and Romans. The evidence which Mr Gibbon produces in proof of what he asserts concerning these opinions of the ancient Gauls is partial, and far from being satisfactory. They did indeed assert and believe the soul to be immortal; but this doctrine was blended with a number of absurdities still grosser than those which characterized the popular religion of the Greeks and Romans. The latter was the superstition of a civilized people, among whom reason was unfolded and improved by cultivation, and whose manners were polished and refined. The former was that of barbarians, among whom reason was, as it were, in its infancy, and who were strangers to the improvements of civilization. Accordingly, when hasty observers found that those barbarians were not absolutely strangers to the idea of immortality, they were moved to undue admiration; their surprise at finding more than they expected confounded their understanding, and led them to misconceive and misrepresent. Hence, what ought to be ascribed to the savage ferocity of those rude tribes, has been attributed by mistake to the influence of their belief of a future state.

In the law of Moses, it must be allowed that this doctrine is not particularly explained nor earnestly inculcated. The author of the *Divine Legation of Moses* has founded upon this fact an ingenious theory, which we shall elsewhere have occasion to examine, and has supported it with great and various erudition. The reason why this doctrine was not more fully explained to the Jews, we shall not pretend to assign, at least in this place; but we cannot help thinking, that it was more generally known among the Jews than Mr Gibbon and Bishop Warburton are willing to allow. Though it be not strongly inculcated in their code of laws, yet there is some reason to think that it was known and generally prevalent among them long before the Babylonian captivity; and in different passages in the writings of Moses it is mentioned or alluded to in an unequivocal manner. In the history of the patriarchs, it appears that this doctrine was known to these "gray fathers;" and it seems to have had a strong influence on the mind of Moses himself. Were David and Solomon strangers to this doctrine? We cannot here specify minute particulars; but surely all the efforts of ingenuity must be insufficient to torture the Sacred Scriptures of the Old Testament, so as to prove that they contain nothing concerning the doctrine of a future state except in the writings of the later prophets, and that even in these it is only darkly insinuated. Were the Jews, in the earlier stage of their history, so totally secluded from all intercourse with other nations, that a doctrine of so much importance, and more or less known to all around, could not be communicated to them? The Pharisees admitted traditions, and set upon them an undue value; yet they appear to have been considered as the most orthodox of the different sects which prevailed among the Jews; for the Sadducees were regarded as innovators and infidels.

But though we are of opinion that the ingenious historian ascribes to the doctrine of the Greek and Roman phi-

losophers, concerning the immortality of the human soul, as well as the notices respecting a future state which formed part of the popular superstitions of those nations, less influence on the moral sentiments and conduct of mankind than what they really exerted; and though we cannot agree with him in allowing that the ideas of the immortality of the soul and of a future state, which were entertained by the Gauls and some other rude nations, were much superior in their nature, or much happier in their influence, than those of the Greeks and Romans; and though, from what is contained in the Old Testament, we are disposed to think that the Jews knew somewhat more concerning the immortality of the human soul, and a future state in which human beings are destined to exist, than Mr Gibbon represents them to have known; yet still we are very sensible, and very well pleased to admit, that "life and immortality were brought to light through the gospel."

The doctrine of a future life, as it was preached by the first Christians, was established on a more solid basis than that on which it had been before maintained; it was freed from every absurdity, and so much improved, that its influence, which, as explained by heathen poets and philosophers, must be confessed to have been in many instances doubtful, now became favourable only to the interests of piety and virtue, and that in no ordinary degree. It undoubtedly contributed to the successful propagation of Christianity; for it was calculated to attract and to please the speculating philosopher, as well as the simple unenlightened votary of the vulgar superstition. The views which it exhibited were distinct; and all was plausible and rational, being demonstrated by the fullest evidence. But the happiness which it promised was of a less sensual nature than the enjoyments which the heathens expected in Elysium; and it would therefore appear less alluring to those who were not capable of entertaining refined ideas, or who preferred the gratifications of the senses in the present life to every other species of good. If the first Christians rejoiced in the hope of beholding all the votaries of Pagan idolatry afflicted with the torments of hell in a future state, and boasted of these hopes with inhuman exultation, they in all probability irritated rather than alarmed those whom they sought to convert from that superstition. The heathens, assailed with such denunciations, might be moved to regard with indignant scorn the preacher who pretended that the beings whom they venerated as gods, heroes, and wise men, were condemned to a state of unspeakable and endless torment. Every feeling of the heart would revolt at the idea of a parent, a child, a husband, a wife, a friend, a lover, or a mistress, but lately lost and still lamented, being consigned to eternal torments for actions and opinions which they had deemed highly agreeable to superior powers.

With respect, then, to the influence of this secondary cause in promoting the propagation of Christianity, we may conclude that the circumstances of the heathen world were less favourable to that influence than Mr Gibbon pretends; that the means by which he represents the primitive Christians to have improved its efficacy, were some of them not employed, and others rather likely to weaken than to strengthen it; and that therefore more is attributed to the operation of this cause than it could possibly produce.

Third cause.

The third cause, the miraculous powers of the primitive church, is with good reason represented as having conduced to the conviction of infidels. Mr Gibbon's reasonings under this head are, that numerous miraculous works of the most extraordinary kind were ostentatiously performed by the first Christians; that, however, from the difficulty of fixing the period at which miraculous powers ceased to be communicated to the Christian church, and from some other circumstances, there is reason to suspect, as is darkly insinuated, that they were merely the pretences of imposture; and that the heathens having been happily prepared to receive them as real by the many wonders nearly of a similar nature to which they were accustomed in their former superstition, the miracles which the first Christians employed to give a sanction to their doctrines contributed in the most effectual manner to the propagation of Christianity.

In reply to what is here advanced, it may be suggested, that the miracles recorded in the New Testament as having been performed by the first Christians when engaged in propagating their religion, are established as true, upon the most indubitable evidence which human testimony can give to any facts. Mr Hume, who was too fond of employing his ingenuity in undermining truths generally received, has endeavoured to prove that no human testimony, however strong and unexceptionable, can afford sufficient evidence of the reality of a miracle; but his reasonings on this head, which once excited doubt and wonder, have since been completely refuted; and mankind still continue to acknowledge, that though we are all liable to mistakes, and exposed to imposition, yet human testimony may afford the most convincing evidence of the most extraordinary and even supernatural facts. We cannot be expected to enter, in this place, into a particular examination of the miracles ascribed to the primitive age of the church. An inquiry into these will occupy a prominent place under the appropriate head of THEOLOGY, to which the reader is accordingly referred. We may, however, consider it as an undeniable and a generally acknowledged fact, that those miracles were real, and that they contributed, in a very eminent manner, to the propagation of Christianity. But it is evident that genuine miracles are not to be ranked among the natural and *secondary* causes.

It was long the current opinion, even among Protestants, that a miraculous power continued for several centuries to reside in the Christian church. When Dr Middleton controverted this opinion in his Free Inquiry, he encountered the most vehement and acrimonious opposition; and many of the clergy, with Archbishop Secker at their head, thought themselves warranted in representing this lingering power as an article of faith. But the progress of reason, though slow, is commonly certain; and the late bishop of Lincoln, Dr Kaye, ventured to express himself in the following terms:—"My conclusion then is, that the power of working miracles was not extended beyond the disciples, upon whom the apostles conferred it by the imposition of their hands."[1]

The heathens were no strangers to pretended miracles and prophecies, and other seeming interpositions of superior beings disturbing the ordinary course of nature and of human affairs; but the miracles to which they were familiarized had been so often detected to be tricks of imposture or pretences of mad enthusiasm, that, instead of being prepared to witness or to receive accounts of new miracles with easy credulity, they must have been in general disposed to view them with jealousy and suspicion.[2] Besides, the miracles to which they had been accustomed, and those performed by the apostles and the first preachers of Christianity, were directly contradictory, and there-

fore the one could receive no assistance from the other. Yet notwithstanding what has been advanced above, we must acknowledge, that as disagreements with respect to the principles and institutions of their religion very early arose among Christians, so they likewise sought to extend its influence, at a very early period, by the use of pious frauds, which appear to have sometimes served the immediate purposes for which they were employed, though eventually they proved highly injurious to the cause of Christianity itself.

We conclude, then, that Christianity was indebted to the influence of miracles in a considerable degree for its propagation, but that the real miracles of our Saviour and his apostles were not among the *secondary* causes of its success; that the heathens who were to be converted were not very happily prepared for receiving the miracles of the gospel with blind credulity; that, as it is possible to discern between sufficient and insufficient evidence, so it is not more difficult to distinguish between true and false miracles; and, lastly, that false miracles were soon employed by Christians as engines to support and propagate their religion, and perhaps not unsuccessfully, but were, upon the whole, more injurious than serviceable to the cause which they were called in to maintain.

Fourth cause.

The fourth of this series of secondary causes, which the author supposes to have been adequate to the propagation of Christianity, is the virtue of the primitive Christians, which he is willing to attribute to other and less generous motives, rather than to the pure influence of the doctrines and precepts of their religion.

The first converts to Christianity were most of them originally persons of the lowest and most worthless characters. The wise, the mighty, and those who were distinguished by specious virtues, were in general perfectly satisfied with their actual circumstances and future prospects. People whose minds were naturally weak, unenlightened, or oppressed with the sense of atrocious guilt, and who were infamous, or outcasts from society, were eager to grasp at the hopes which the gospel held out to them. When, after enlisting under the banner of Christ, they began to consider themselves as "born again to newness of life;" remorse and fear, which easily prevail over weak minds; selfish hopes of regaining their reputation, and attaining to the honours and happiness of those mansions which Jesus was said to have gone to prepare; and a desire to raise the honour and extend the influence of the society of which they were become members; all operated powerfully, so as to enable them to display both active and passive virtue in an extraordinary degree. Their virtues did not flow from the purest and noblest source, yet they attracted the notice and moved the admiration of mankind. Of many who admired, some were eager to imitate, and, in order to this, thought it necessary to adopt the same principles of action. Their virtues, too, were rather of that species which excite wonder, because uncommon, and not of essential utility in the ordinary intercourse of society, than of those which are indispensably necessary to the existence of social order, and contribute to the ease and convenience of life. Such virtues were well calculated to engage the imitation of those who had failed egregiously in the practice of the more social virtues. Thus they practised extraordinary but useless and unsocial virtues, from no very generous motives; and those virtues drew upon them the eyes of the world, and induced numbers to embrace their faith.

We must, however, declare, that this is plainly an uncandid account of the virtues of the primitive Christians, and of the motives from which they originated. The social virtues are strongly recommended in the gospel. No degree of mortification or self-denial, or seclusion from the ordinary business and amusements of social life, was required of the early converts to Christianity, except what was indispensably necessary to wean them from the irregular habits in which they had before indulged, and which had rendered them nuisances in society, and to form them to new habits equally necessary to their happiness and their usefulness in life. We allow that they practised virtues which in other circumstances would, however splendid, have been unnecessary; but, in the difficult circumstances in which the first Christians were placed, the virtues which they practised were in the highest degree social. The most prominent feature in their character was their continuing to entertain sentiments of generous benevolence, and to discharge scrupulously all the social duties, towards those who exercised neither charity nor humanity, and frequently not even bare integrity and justice, in their conduct towards them.

It cannot be said with truth that such a proportion of the primitive Christians were people whose characters had been infamous, and their circumstances desperate, as that the character of the religion which they embraced should suffer from this circumstance. Nor were they only the weak and illiterate whom the apostles and their immediate successors converted by their preaching. The criminal, to be sure, rejoiced to hear that he might obtain absolution of his crimes; the mourner was willing to receive comfort; and minds of refined and generous feelings were deeply affected with that goodness which had induced the Son of God to submit to the punishment due to sinners: but the simplicity, the rationality, and the beauty of the Christian system, likewise prevailed in numerous instances over the pride and prejudices of the great and the wise, and in instances sufficiently numerous to vindicate the Christian church from the aspersions by which it has been represented as being in the first period of its existence merely a body of criminals and idiots.

The principles, too, from which the virtues of the first Christians originated, were not peculiarly mean and selfish: on the contrary, they seem to have been uncommonly sublime and disinterested. Remorse in the guilty mind is a natural and reasonable sentiment; and the desire of happiness in every human breast is equally so. It is uncandid, therefore, to cavil against the first Christians for being, like the rest of mankind, influenced by these sentiments. And when we behold them overlooking temporary possessions and enjoyments, extending their views to futurity, and "living by faith;" when we observe them "doing good to those who hated them, blessing those who cursed them, and praying for those by whom they were despitefully used and persecuted;" we cannot deny that their virtues were of the most generous and disinterested kind.

We allow, then, that the virtues of the first Christians must have contributed to the propagation of their religion; but it is with pain that we observe the historian studiously labouring to misrepresent the principles from which those virtues arose; and not only the principles themselves, but also the importance of the actions and conduct which naturally sprung from them.

Fifth cause.

The fifth cause was the mode of church government adopted by the first Christians, by which they were knit together in one society, and preferred the church and its interests to their country and civil concerns. We do not deny that the mutual attachment of the primitive Christians contributed to spread the influence of their religion; and the order which they maintained, by being animated with this spirit of brotherly love, and with an ardent zeal for the glory of God, must no doubt have produced those happy effects among them which order and regularity produce on every occasion when they are strictly observed.

But whether the form of church government, which was gradually established in the Christian church, was actually the happiest that could possibly have been adopted; or whether, by establishing a distinct society, with separate interests, within the Roman empire, it contributed to the dissolution of that mighty fabric; we cannot here pretend to inquire. These are subjects of discussion with respect to which we may with more propriety endeavour to satisfy our readers under another head.

From the whole, then, of this review of what Mr Gibbon has so speciously advanced concerning the influence of these five secondary causes in the propagation of the gospel, we think ourselves warranted to conclude, that the zeal of the first Christians was not, as he represents it, intolerant; that the doctrine of the immortality of the human soul was somewhat better understood in the heathen world, particularly among the Greeks and Romans, and the Jews, than he represents it to have been, and had an influence somewhat happier than that which he ascribes to it; that the additional circumstances by which, he informs us, the first preachers of Christianity improved the effects of this doctrine, were far from being calculated to allure converts; that the heathens, therefore, were not quite so well prepared for an eager reception of this doctrine as he would persuade us that they were, and, of consequence, could not be influenced by it in so considerable a degree in their conversion; that real and unquestionable miracles, performed by our Saviour, and the first race of Christians, contributed signally to the propagation of Christianity, but are not to be ranked among the secondary causes of its diffusion; that weakness and blind zeal did at times employ pretended miracles for the same purpose not altogether ineffectually; that though these despicable and wicked means might be in some instances successful, yet they were, upon the whole, much more injurious than beneficial; that the virtues of the primitive Christians arose from the most generous and noble motives, and were in their nature and tendency highly favourable to social order, and to the comfort of mankind in the social state; and, lastly, that the order and regularity of church government, which were gradually established among the first Christians, contributed greatly to maintain the dignity and spread the influence of their religion, but tended in no degree to disjoin them from their fellow-subjects, or to render them inimical to the welfare of the state of which they were members. Upon the whole, therefore, we do not see that these secondary causes were equal to the effects which have been ascribed to them; and it seems undeniable that others of a superior kind must have co-operated in the diffusion of Christianity.[1]

CHRISTIANS, those who profess the religion of Jesus Christ. The name Christians, as we read in the Acts of the Apostles, was first given at Antioch, in the year 42, to those who believed in Jesus Christ. Till that time they were called *disciples*.

The first Christians distinguished themselves in the most remarkable manner by their conduct and their virtues. The faithful, whom the preaching of St Peter had converted, hearkened attentively to the exhortations of the apostles, who failed not carefully to instruct them, as persons who were entering upon an entirely new course of life. They went every day to the temple with one heart and one mind, and continued in prayers; doing nothing different from the other Jews, because the time had not yet come to separate from them. But they made a still greater progress in virtue; for they sold all that they possessed, and distributed their goods in proportion to the wants of their brethren. They "ate their meat with gladness and singleness of heart, praising God, and having favour with all the people."

The Jews were the first and the most inveterate enemies of the Christians, whom they put to death as often as they had it in their power; and when they revolted against the Romans in the time of the emperor Hadrian, Barcochebas, the head of that revolt, employed against the Christians the most barbarous punishments, in order to compel them to blaspheme and renounce Jesus Christ. We find indeed that, even in the third century, they endeavoured to get into their hands Christian women, in order to scourge and stone them in their synagogues. They cursed the Christians solemnly three times a day in their synagogues, and their rabbin would not suffer them to converse with Christians upon any occasion. Nor were they contented merely to hate and detest them. They dispatched emissaries all over the world in order to defame the Christians, and to spread all sorts of calumnies against them; they accused them of many things absurd or detestable, and, among these, of worshipping the sun and the head of an ass; they reproached them with idleness, and with being a useless unprofitable race; they charged them with treason, and with endeavouring to erect a new monarchy in opposition to that of Rome; they affirmed, that, in celebrating their mysteries, they used to kill a child and eat its flesh; and they accused them of the most shocking incests, and of beastly intemperance in their feasts of charity. But the lives and behaviour of the first Christians were sufficient to refute all that was said against them, and evidently demonstrated that these accusations were mere calumnies and the effect of inveterate malice.

Pliny the Younger, who was governor of Pontus and Bithynia between the years 103 and 105, gives a particular account of the Christians of that province, in a letter which he wrote to the emperor Trajan, of which the following is an extract: "I take the liberty to give you an account of every difficulty which arises to me. I have never been present at the examination of the Christians; for which reason I know not what questions have been put to them, nor in what manner they have been punished. My behaviour towards those who have been accused to me has been this. I have interrogated them in order to know whether they were really Christians. When they have confessed it, I have repeated the same question two or three times, threatening them with death if they did not renounce this religion. Those who have persisted in their confession, have been, by my order, led to punishment. I have even met with some Roman citizens guilty of this phrenzy, whom, in regard to their quality, I have set apart from the rest, in order to send them to Rome. These persons declare, that their whole crime, if they are guilty, consists in this, that, on certain days, they assemble before sunrise, to sing alternately the praises of Christ, as of a God, and to oblige themselves, by the performance of their religious rites, not to be guilty of theft or adultery, to observe inviolably their word, and to be true to their trust. This deposition has obliged me to endeavour to in-

form myself still further of this matter, by putting to the torture two of their women servants, whom they call *deaconesses;* but I could learn nothing more from them than that the superstition of these people is as ridiculous as their attachment to it is astonishing."

There is still extant a justification, or rather panegyric, of the Christians, pronounced by the mouth of a heathen prince. It is a letter of the emperor Antoninus, written in the year 152, in answer to a charge by the states of Asia, which had accused the Christians of being the cause of some earthquakes which had happened in that part of the world. The emperor advises them to "take care, lest, in torturing and punishing those whom they accused of Atheism (meaning the Christians), they should render them more obstinate, instead of prevailing upon them to change their opinion; since their religion taught them to suffer with pleasure for the sake of God." As to the earthquakes which had happened, he put them in mind, that "they themselves are always discouraged, and sink under such misfortunes; whereas the Christians never discovered more cheerfulness and confidence in God than upon such occasions." He tells them, that "they pay no regard to religion, and neglect the worship of the Eternal; and, because the Christians honour and adore Him, therefore they are jealous of them, and persecute them even to death." He concludes with these words: "Many of the governors of provinces have formerly written to my father concerning them; and his answer always was, that they should not be molested or disturbed, provided they quietly submitted to the authority of the government. Many persons have likewise consulted me upon this affair, and I have returned the same answer to them all; namely, that if any one accuses a Christian merely on account of his religion, the accused person shall be acquitted, and the accuser himself punished." This ordinance, according to Eusebius, was publicly displayed at Ephesus, in an assembly of the states.

It is not a difficult matter to discover the causes of the many persecutions to which the Christians were exposed during the first three centuries. The purity of the Christian morality, being in direct contrast with the corruption of the heathens, was doubtless one of the most powerful motives of the public aversion; and to this may be added the many calumnies unjustly spread abroad concerning them by their enemies, particularly the Jews; a circumstance which occasioned so strong a prejudice against them, that the Pagans condemned them without inquiring into their doctrine, or permitting them to defend themselves. Besides, their worshipping Jesus Christ as God was contrary to one of the most ancient laws of the Roman empire, which expressly forbade the acknowledging of any God who had not been approved as such by the senate.

But notwithstanding the violent opposition made to the establishment of the Christian religion, it gained ground daily, and very soon made a surprising progress in the Roman empire. In the third century, there were Christians in the camp, in the senate, in the palace, in short, everywhere but in the temples and the theatres; they filled the towns, the country, the islands; men and women of all ages and conditions, and even those of the first dignities, embraced the faith; insomuch that the Pagans complained that the revenues of their temples were ruined. So numerous were they in the empire, that, as Tertullian expresses it, were they to have retired into another country they would have left the Romans to inhabit a solitude.

CHRISTIANSAND, a fortified seaport-town of Norway, capital of a stift of the same name, on a fiord of the Skagerrack, in Lat. 58. 8. N., Long. 8. 4. E. Pop. (1845) 8548. The town, for the most part of wood, is regularly built, and the streets are wide. The cathedral is a fine building of gray stone, and after those of Drontheim and Stavangar it is the finest in Norway. The principal branch of industry is shipbuilding; and a considerable trade is carried on in lobsters and timber. The harbour is one of the best in Norway.

CHRISTIANSTAD, a fortified town of Sweden, capital of the province of the same name, on the Helge river, where it forms a small lake, about 8 miles from its mouth in the Baltic. The town, though regularly built, consists principally of wooden structures. Chief manufactures, linen and woollen goods and gloves. Pop. 4500. At the mouth of the river is Ahus, the port of Christianstad, by means of which it carries on some trade in pitch, tar, alum, potash, and timber.

CHRISTINA, queen of Sweden, only daughter of Gustavus Adolphus, was born in 1626, and succeeded to the crown in 1632, when only six years of age. The solid and masculine education which she received from her father and guardians gave her, as she has expressed in her memoirs, an invincible antipathy to the employments and conversation of women; and she had all the awkwardness of a man in performing the little duties which generally fall to the share of her sex. In her youth she was fond of violent exercises; and her amusements generally consisted in feats of strength and agility. She also showed considerable ability and taste for abstract speculations; and made herself familiar with languages and the sciences, particularly with that of legislation. She derived her knowledge of ancient history from original sources: Polybius, Thucydides, and Tacitus, were her favourite authors. Independent of her acknowledged genius and ability, her position as the sovereign of a powerful kingdom made almost all the princes in Europe aspire to her hand. Amongst these were the prince of Denmark, the elector Palatine, the elector of Brandenburg, the king of Spain, the king of the Romans, Don John of Austria, Stanislaus king of Poland, John Casimir his brother, and Charles Gustavus duke of Deux Ponts, of the Bavarian Palatinate family, son of the great Gustavus's sister, and consequently her first cousin. To this nobleman, as well as to all his rivals, she constantly refused her hand, at the same time that she caused him to be appointed her successor by the states. Political interests, religious differences, and conflicting tastes, furnished Christina with pretences for rejecting all her suitors; but her real motives were love of independence, and a strong aversion, even from her infancy, to the marriage yoke. "Do not force me to marry," said she to the states, "for if I should have a son it is not more probable that he should be an Augustus than a Nero."

One of the most complicated affairs which occupied her attention was the peace of Westphalia, in which many conflicting interests were to be reconciled, and many claims to be decided. It was concluded in the month of October 1648. The success of the Swedish arms rendered Christina the arbitress of this treaty, at least in regard to the affairs of Sweden, to which the peace confirmed the possession of many important countries. No public event of importance took place during the rest of Christina's reign; for there were neither wars abroad nor troubles at home. Her reign was distinguished by an active encouragement of learning and genius. She drew to her court all the distinguished men of her time, including Grotius, Pascal, Bochart, Descartes, Gassendi, Saumase, Naude, Vossius, Heinsius, Meibom, Scudéry, Ménage, Lucas, Holstentius, Lambecius, Bayle, and many others. The arts never fail to immortalize the prince who protects them; and almost all these illustrious persons have rendered their patroness illustrious, either in poems, letters, or literary productions of some other kind.

Though Christina at first was fond of royal power and splendour, yet she soon began to feel embarrassed and restrained; and the same love of independence which had determined her against marriage at last made her weary of the

Christmas Day.

crown. Accordingly, as it grew more and more irksome to her, she resolved to abdicate; and, in 1652, communicated her resolution to the senate. The senate zealously remonstrated against it, and was joined by the people, nay, even by Charles Gustavus himself, who was to succeed her. She yielded to their importunities, and continued to sacrifice her own pleasure to the will of the public till the year 1654, when she carried her design into execution. Besides abdicating her crown, she also abjured her religion; an act which deeply wounded her Protestant subjects. No prince ever showed so much joy on being elevated to the throne as Christina did in quitting hers. When she came to a little brook which separates Sweden from Denmark, she got out of her carriage, and leaping on the other side, cried out in a transport of joy, "At last I am free, and out of Sweden, whither, I hope, I shall never return." She dismissed her women, and laying aside the habit of her sex, "I would become a man," said she; "yet I do not love men because they are men, but because they are not women." She made her abjuration at Brussels, where she saw the great Condé, who, after his defection, made that city his asylum. "Cousin," said she, "who would have thought, ten years ago, that we should have met at this distance from our respective countries?" During her residence in France she excited universal disgust by her open contempt and violation of the customs of the country. She treated the ladies of the court with the greatest rudeness, and when they came to embrace her, she exclaimed (alluding to her male attire), "What a strange eagerness these women have to kiss me! Is it because I look like a man?"

The murder of Monaldeschi, her master of the horse, on account of the betrayal of some secret, has left a deep stain on her character, notwithstanding the apologies that have been offered by Leibnitz and others. It is too much in keeping with expressions constantly used by Christina in her letters in regard to those with whom she was offended; for she scarcely ever signified her displeasure without threatening the life of the offender. "If you fail in your duty," said she to her secretary, whom she sent to Stockholm after her abdication, "not all the power of the king of Sweden shall save your life, though you should take shelter in his arms." With a musician who had quitted her service for that of the Duke of Savoy she was so enraged as to resort to a threat of murder. "He lives only for me; and if he does not sing for me he shall not sing long for anybody else."

The horror and indignation with which she was regarded in France, induced her to retire again to Rome, whence, on the death of Gustavus, in 1660, she went to Sweden; but meeting everywhere with hostility and coldness from the people, she quickly retraced her steps. Once more having quarrelled with the pope, she set out for her former dominions, but proceeded no further than Hamburgh, whence she again returned to Rome, and died in 1689.

Upon the whole, her character presents a strange combination of faults and foibles, pushed to the most extravagant excess. She says of herself, "that she was mistrustful, ambitious, passionate, haughty, impatient, contemptuous, satirical, incredulous, undevout, of an ardent and violent temper, and extremely amorous;" a disposition, however, to which, at least according to her own account, her pride and her virtue were always superior. See SWEDEN.

CHRISTMAS DAY, a festival of the Christian Church, observed on the 25th of December, in memory of the nativity of Jesus Christ. The day, however, now kept as Christmas cannot be that of the nativity of our Lord, for the reason assigned long ago by Shaw and others, viz., that in December, which is the height of the rainy season in Judæa, neither flocks nor shepherds could have been at night in the fields of Bethlehem, which we are told was the case at the nativity of Christ. As to the antiquity of this festival, the first traces we find of it are in the second century, about the time of the Emperor Commodus. The decretal epistles indeed carry it a little higher, and state that Telesphorus, who lived in the reign of Antoninus Pius, ordered divine service to be celebrated, and an angelical hymn to be sung, the night before the nativity of our Saviour. We have a melancholy proof that it was observed before the times of Constantine; for whilst the persecution raged under Diocletian, who then kept his court at Nicomedia, that prince, among his many acts of cruelty, finding multitudes of Christians assembled together to celebrate Christ's nativity, commanded the church doors where they were met to be shut, and fire to be put to it, which in a short time reduced the church and all within it to ashes.

In all civilized countries the annual recurrence of Christmas was celebrated with festivities of various kinds. In none however was it more joyfully welcomed than in England, where even still all the "old honour" has not altogether fled. In that country it was the custom on Christmas eve, after the usual devotions were over, to light large candles and throw on the hearth a huge log, called the Yule Log or Christmas Block. This latter practice is still observed to a considerable extent in England, especially in the northern counties. At court, and in the houses of the wealthy, an officer, named the *Lord of Misrule*, was appointed to superintend the revels; and even in Scotland a similar functionary used to be appointed under the title of the *Abbot of Unreason*, till the year 1555, when the office was abolished by act of parliament. The reign of the Lord of Misrule began on All-Hallow Eve and lasted till Candlemas day. The favourite pastimes over which he presided were gaming, music, conjuring, dipping for nuts and apples, dancing, fool plough, hot cockles, blind-man's buff, &c. All these recreations were regarded with the utmost horror by the Puritans, who cursed them with a wrath that was at best fanatical. The favourite dishes for breakfast and supper at this season were the boar's head with an apple or orange in the mouth, and set off with rosemary, plum pudding, and mince pies. The latter dish was regarded with peculiar aversion by the Puritans, and it was therefore a point of orthodoxy to partake of it. The houses and churches were decked with evergreens, especially with misletoe, to which a traditionary sacredness has attached since the days of the Druids.

Christophers.

CHRISTOPHERS, ST, or ST KITTS, one of the British West India Islands, 46 miles W.N.W. of Antigua, Lat. 17. 20. N., Long. 62. 40. W. It is about 20 miles in length from N.W. to S.E., with an average breadth of 4 miles, but narrowing towards its S.E. extremity. It takes its name from Columbus, by whom it was discovered in 1493, at which time it was densely peopled by Caribs. In 1623 a party of English under one Warner first settled on the island, and soon afterwards a party of French arrived under M. D'Esnambue. The English lived for some time on friendly terms with the natives; but having unwarrantably seized on some of their lands, and being apprehensive that the Caribs would retaliate, they treacherously surprised them during the night, murdered above one hundred, and expelled the rest, reserving the most handsome of the young women. The colony, however, after this inhuman outrage, was far from flourishing, and the two leaders were compelled to return to their respective countries for recruits. Warner returned with about 400, and a plentiful supply of necessaries. The greater part of D'Esnambue's recruits perished at sea, and the remainder reached the island in a wretched condition. A treaty was now signed, fixing the territory of each party, the upper part, Capis-terre, being allotted to the French, and the lower part, Basse-terre, to the English. The island was afterwards seized by the Spaniards; but these invaders departed in a short time, and the tranquillity of the settlement was restored. In the numerous wars between the

two mother countries, St Christophers suffered severely, and was repeatedly laid waste by the French. So completely was this done in 1705, that the parliament of England was obliged to distribute L.100,000 amongst the unhappy sufferers. At the peace of Utrecht the island was wholly ceded to Britain, and the French possessions were sold for the benefit of the English government. In the year 1782 it was taken possession of by a French armament, but again restored in the year following. St Christophers is computed to contain 43,726 acres of land, about one-half of which is under cultivation. This island has a beautiful and picturesque appearance. In the interior are several mountains, one of which, Mount Misery, an extinct volcano, towers to an elevation of 3711 feet above the level of the sea. The barrenness of these rugged, bleak, and precipitous eminences is amply compensated by the luxuriant vegetation of the plains, which have been cultivated to the very utmost. The soil is rich, and yields abundant crops of sugar, the staple product of the island. The sugar exported in 1850 amounted to 4708 hhds., and in 1851 (a very favourable year) to 7270. In 1852 a long-prevailing drought caused a partial failure of the crop, and considerably affected the revenue. Revenue (1851) L.17,902, (1852) L.13,265; expenditure (1851) L.14,672, (1852) L.13,090; imports (1851) L.112,748, (1852) L.76,680; exports (1851) L.126,610, (1852) L.91,741. Pop. (1812) 23,177. In 1851 the number of pupils attending the Church schools was 796, the Wesleyan schools 850, and the Moravian schools 885. The climate is healthy, but violent hurricanes occasionally occur. The island is governed by a lieutenant-governor, and sends 10 members to the house of assembly of the Leeward Islands at Antigua.

Basse-terre, the capital town, is situated at the S.W. end of the island, and at the mouth of a river which disembogues its waters into a bay called Basse-terre road. It possesses many good houses, and a large and handsome square, and carries on a considerable trade. Its harbour is defended by several batteries. Pop. 6500.

CHROMATIC, a kind of music which proceeds by several semitones in succession. The word is derived from the Greek χρωμα, which signifies *colour*. For this denomination several causes have been assigned, of which none appears certain, and all are equally unsatisfactory. Instead, therefore, of fixing upon any, we shall offer a conjecture of our own, namely, that as χρωμα not only signifies a *colour*, but also a shade of a colour by which it melts into another, or what the French call *nuance*, so the word in this sense is highly applicable to semitones, which being the smallest interval allowed in the diatonic scale, most easily run into one another. In order to learn the reasons assigned by the ancients for this denomination, and their various divisions of the chromatic species, the reader may consult the same article in Rousseau's Musical Dictionary. At present this species consists in giving such a procedure to the fundamental bass, that the parts in the harmony, or at least some of them, may proceed by semitones, as well in rising as in descending, which is most frequently found in the minor mode, from the alterations to which the sixth and seventh notes are subjected, by the nature of the mode itself.

The successive semitones used in the *chromatic* species are rarely of the same kind, but alternately major and minor, that is to say, chromatic and diatonic; for the interval of a minor tone contains a minor or chromatic semitone, and another which is major or diatonic, a measure which temperament renders common to all tones; so that we cannot proceed by two minor semitones which are conjunctive in succession without entering into the enharmonic species, but two major semitones twice follow each other in the chromatic order of the scale.

The most certain procedure of the fundamental bass to generate the chromatic elements in ascent, is alternately to descend by thirds and rise by fourths, whilst all the chords carry the third major. If the fundamental bass proceeds from dominant to dominant by perfect cadences avoided, it produces the chromatic in descending. To produce both at once, the perfect and broken cadences are interwoven, but at the same time avoided.

At every note in the chromatic species, the tone must be changed; that succession ought to be regulated and limited, for fear of deviation. For this purpose it will be proper to recollect that the space most suitable to chromatic movements is between the extremes of the dominant and the tonic in ascending, and between the tonic and the dominant in descending. In the major mode one may also chromatically descend from the dominant upon the second note. This transition is very common in Italy; and, notwithstanding its beauty, begins to be a little too common amongst us.

The chromatic species is admirably fitted to express grief and affliction; and these sounds boldly struck in ascending are powerfully effective. Their influence is no less magical in descending; it is then that the ear seems to be pierced with real groans. Attended with its proper harmony, this species appears proper to express everything; but its completion, by concealing the melody, sacrifices a part of its expression; and for this disadvantage, arising from the fulness of the harmony, it can only be compensated by the nature and genius of the movement. We may add that, in proportion to the energy of this species, the composer ought to use it with greater caution and parsimony, like those elegant viands which, when profusely administered, immediately surfeit us with their abundance, as much as they delight us when enjoyed with temperance and moderation. See Music.

CHROMATICS.

The gradual progress of scientific investigation has continued to add, from year to year, a multitude of new discoveries to our knowledge of experimental and physical optics; and no department of this subject has received additions so diversified and so important as those which relate to the phenomena of colours, which have been displayed, with a thousand brilliant and unexpected transformations, under circumstances that in former times could never have been suspected of exhibiting anything resembling them. The successive experiments and calculations of Dr Thomas Young (1801), Dr Wollaston (1802), Mr Malus (1810), Mr Arago, Mr Biot, Dr Brewster,[1] Dr Seebeck, and Mr Fresnel, have all contributed very essentially to the extension and illustration of this interesting branch of science. But, notwithstanding all that has hitherto been done, it appears to be utterly impracticable, in the present state of our knowledge, to obtain a satisfactory explanation of all the phenomena of optics, consi-

[1] Now Sir David Brewster.

dered as mechanical operations, upon any hypothesis respecting the nature of light that has hitherto been advanced. It will, therefore, be desirable to consider the facts which have been discovered, with as little reference as possible to any general theory; at the same time, it will be absolutely necessary, as a temporary expedient, to borrow from the undulatory system Dr Young's law of the interference of light, as affording the only practicable mode of connecting an immense variety of facts with each other, and of enabling the memory to retain them; and this adoption will be the more unexceptionable, as many of the most strenuous advocates for the projectile theory have been disposed, especially since the experiments of Mr Arago and Mr Fresnel, to admit the truth of the results of all the calculations in which this law has been employed. The details of its application to particular cases, together with an examination of the phenomena of polarisation and of oblique refraction, will occupy the principal part of this article; but it will also be necessary to premise an account of the few cases of the exhibition of colours which appear to be independent of its operation.

Sect. I.—*Of the Separation of Colours by Refraction.*

The separation of white light into different colours, as its component parts, by refraction, though firmly established as an optical fact by Newton, had been in general somewhat negligently examined as to its details, until Dr Wollaston pointed out the inaccuracy of the common subdivision of the colours of the prismatic spectrum into seven different species. There is little reason to doubt that white light consists of an infinite number of rays, varying gradually among each other, without any marked distinctions, and continued, on the one hand, into the dark chemical rays, and, on the other, into the rays of invisible heat; and that all these varieties are separable from each other by refraction, and preserve always a distinct and constant refrangibility. The species of homogeneous light, however, distinguishable from each other by the eye, are only five,—red, yellow, green, blue, and violet; which are uniform in their appearance, and well-defined in their limits, whenever a perfect spectrum is correctly exhibited, whether obtained by interposing a prism between the eye and a small, or rather narrow bright object, or between a lens and the image of such an object formed in its focus; while, in the common method of admitting a beam of the sun's light through a prism, without either employing a lens, or previously limiting the angular extent of the beam, it is obvious that there must be a double source of the mixture of colours; and hence has arisen the Newtonian division of the spectrum into seven parts, which were somewhat fancifully compared, with respect to their extent, to the intervals of the minor diatonic scale in music; although it has been shown by Dr Blair, and still more fully by Dr Brewster, that their proportions are liable to very great variations, according to the nature of the refracting substances employed.

Dr Brewster has remarked, that as, according to the fundamental law of refraction, a prism with a large angle must occasion a dispersion of the several colours somewhat greater than two smaller prisms of the same substance, having together an equal mean refractive power; so also the dispersion of the most refrangible or violet rays amongst themselves will be always somewhat greater in a prism with a larger angle, than in two smaller prisms having an equal mean dispersive power. Hence the green and blue will be less removed from the red towards the violet by the single prism, the refraction of the green remaining in defect, when compared with the mean of the whole. So that, if the two prisms be employed to correct the mean dispersion of the single one, and the extreme rays of the spectrum be brought to a perfect coincidence, the refraction of the green by these prisms being comparatively in excess, the green rays will be found on the side towards which their refraction tends to carry them; and the two extreme portions of red and violet will be left together, forming a crimson, on the side towards which the refraction of the larger prism is directed. It is obvious also that if, instead of the two smaller prisms, a single one of an equal angle, but of twice the dispersive power, were substituted, the joint effect would be nearly the same. Dr Brewster has, however, observed, that in almost all such combinations of different substances, the green is on the side towards which the refraction of the larger prism is directed; so that the original proportion of the space occupied by the different rays in the spectrum must be different for different substances. Dr Brewster has found that the violet is the most dispersed by oil of cassia and by sulphur, and least by sulphuric acid and by water; the distribution afforded by these substances appearing to vary from two parts of red, three green, four blue, and three violet, to about four red, three green, three blue, and two violet; while the yellow is always confined to a narrow line.

The immediate effects of the combinations of the primitive colours on the sense of sight afford an illustration of some of the physiological characters of sensation in general. It is well known that a mixture of red and green light produces a simple sensation, perfectly identical with that which belongs to the minute portion of yellow light originally found in the spectrum; and that a mixture of green and violet makes a perfect blue. The blue colour of the flame of spirit of wine, for example, is derived entirely from a mixture of green and violet rays; while the blue light of the lower part of the flame of a candle is shown by the prism to consist of five different portions, belonging to different parts of the spectrum, nearly resembling those which would be distinguished if we looked through a prism at a small portion of a transparent plate of a certain minute thickness. It is obvious, therefore, that the eye has no immediate power of analysing such light; and if we seek for the simplest arrangement, which would enable it to receive and discriminate the impressions of the different parts of the specimen, we may suppose three distinct sensations only to be excited by the rays of the three principal pure colours falling on any given point of the retina, the red, the green, and the violet; while the rays occupying the intermediate spaces are capable of producing mixed sensations, the yellow those which belong to the red and green, and the blue those which belong to the green and violet; the mixed excitement producing in this case, as well as in that of mixed light, a simple idea only: although it must be observed that no homogeneous light can extend its action so far as to excite at once the sensations of the fibres belonging to the red and the violet; so that every crimson must necessarily be a compound colour. A mixture of red and blue light exhibits an effect which appears unintelligible upon the supposition that a compound light ought to produce a colour intermediate between those of its constituent parts; but this difficulty will vanish, if we assume that the blue of the spectrum contains a greater proportion of violet than of green; so that the green is neutralized into a white by a mixture with the red and part of the violet, and the remaining violet gives its character to the whole, either alone, or with a mixture of red, according to the proportions employed.

When we look through a prism at a luminous object of considerable extent, surrounded by a dark space, the spectra belonging to the several parts of the object are mixed with each other, so as to produce a light perfectly

white, except towards the ends of the object, where the extreme parts project beyond each other. At the red end of the spectrum the whole of the red belonging to the extreme point retains its place unaltered, and the green and blue become a greenish yellow, nearly uniform in its appearance, throughout the space which belongs to them, while the place of the violet is scarcely distinguishable from the neighbouring white light; but at the opposite end the violet retains its place and appearance, and the remainder of the length of the spectrum becomes of a green, inclining more or less to blue, and continuing to be very distinctly visible throughout the extent of the simple spectrum, the place of the red included; so that the illuminating power of the red end of the spectrum must be incomparably greater than that of the violet end; as may also be inferred by a direct comparison of the distinctness of objects viewed in these different lights. The portion of light totally reflected at the internal surface of a dense medium, on account of the obliquity of its incidence, is bounded by a fringe or bow resembling the red end of the luminous object viewed through a prism; and the transmitted portion is bounded by the violet and blue fringe; but it requires some caution, in observing these colours, to avoid the optical deception which causes the neighbouring space to appear of the complementary colour, especially when the eye is turned towards it immediately after having received the impression of the colours actually exhibited.

Sect. II.—*Of the Colours of Halos and Parhelia.*

The immediate effect of the different refrangibility of light in the production of colours is sometimes spontaneously exhibited, in the atmospherical phenomena of halos and parhelia, or paraselenes, attending the sun or moon; the edge nearest to the luminary being generally reddish, and the remoter parts more or less green and blue, although without any well-marked separation of the different tints. These appearances had been long ago referred by Mariotte to the refraction of the prismatic crystals of snow floating in the atmosphere, and descending through it in all possible positions, but more especially in a vertical or horizontal direction, on account of the effect of gravity, combined with that of the resistance of the air; and sometimes perhaps, from their connection with other crystals, making angles of 60° with either of these positions. This theory, however simple and satisfactory, had been very unaccountably neglected for more than a century, and even superseded by the awkward and unsupported conjectures of Huygens respecting the existence of spherical or cylindrical particles of hail, including opaque nodules, related to them in a certain constant ratio; or by the equally inadmissible calculation of Newton, which assigns a partial maximum to the density of the light simply refracted through a spherical drop of water when the deviation is about 26°; and it is only a few years since that the doctrine of Mariotte was revived and extended by Dr Young, and approved by Mr Cavendish and Mr Arago.

In some of the highest northern latitudes these appearances of halos and parhelia are almost constant; and in warmer countries they are confined to the light clouds which occupy the higher and colder regions of the atmosphere. The halos are broad circles, with their interior margin tolerably well defined, and about the distance of 22° and 46° from the sun or moon, but less distinctly terminated externally. Now the angle of 22° exactly corresponds to the deviation produced by a prism of ice, with a refracting angle of 60°, when it becomes a minimum from the equality of the angles of incidence and emergence; and in other positions of the prism the deviation increases very slowly, till it becomes a few degrees greater. Hence the breadth of the circles of each colour being considerable, the colours must fall principally on each other, and become very indistinctly separated. The external circle may be referred to the effect of two such refractions in succession. Mr Cavendish seems to have thought the angle somewhat too great to be derived from this source; and he suggested that it might depend on a single refraction by the rectangular terminations of the crystals; but it does not appear that such terminations are very commonly observable; and it may easily be shown that the greatest intensity of the light of a halo formed by two refractions must be at more than twice the distance of the edge of the inner halo, derived from one only.

These halos are commonly accompanied by a white horizontal circle passing through the sun, derived from the reflection of the vertical faces of the crystals, which are scattered equally throughout all possible azimuths. There are also generally coloured parhelia on each side, depending on the refraction of these vertical prisms; they are commonly a little without the halos, because the deviation of the light passing obliquely through these crystals is somewhat greater than that of the light transmitted by the crystals which have their axes perpendicular to the plane of incidence and refraction. For a similar reason, the light passing through the crystals horizontally in various azimuths is variously modified, so as to produce the appearance of inverted arches, touching the halos at their highest points, and sometimes expanding in the form of a pair of wings, with a point of contrary flexure on each side.

The anthelia seem to be referrible to two refractions and an intermediate reflection within the same crystal, causing a deviation of about $120 + 22 = 142°$; and sometimes with two intermediate reflections, producing an angle of $60 + 22 = 82°$ only. It is not, however, very easy to assign a reason for the appearance of an anthelion exactly opposite to the sun, which is said to have been sometimes seen in the horizontal circle; but it has been delineated with the accompaniment of an oblique cross, and of other unusual appearances, which must have been derived from extraordinary forms of the compound crystals of snow existing at the time of the observation in the atmosphere.

Sect. III.—*Of the Colours of the Rainbow.*

The general nature of the primary rainbow was cursorily explained by De Dominis; but Descartes first applied the true law of refraction, which had recently before been discovered, to the determination of the angular magnitude both of this and of the secondary rainbow; although no sufficient reason could be assigned for the appearance of colours in either of them, until Newton ascertained the different refrangibilities of the different kinds of rays; but as soon as this discovery was established, the method of fluxions at once enabled him to determine precisely the limit at which the broad expanse of light belonging to each colour must necessarily terminate in an edge of greater brilliancy; the bright edges of the different colours projecting gradually beyond each other, so as to form a spectrum somewhat mixed, but still approaching to the common appearance of a spectrum obtained by the refraction of a prism; and in fact the angular distances of the exterior termination of the primary rainbow and of the interior of the secondary, from the sun, are found to agree very accurately with the calculation of the extreme deviations of the red rays reflected once and twice respectively within the spherical drops of rain; although

the whole breadth of the coloured appearances is liable to variations dependent on the magnitude of the drops, and belonging to the phenomena of supernumerary rainbows, to be described hereafter.

The light reflected from very small portions of water appears to be incapable of producing a regular rainbow. Thus we scarcely ever see a rainbow in a cloud, unless it has united its drops, so that they begin to descend in the form of rain. Dr Smith has observed this circumstance, and has attributed it to a tendency of the bright edge of the expanse of light to lose its intensity, by being gradually dissipated into the neighbouring dark space; a tendency which he would probably have been much at a loss to explain from any of the received doctrines of optics, but which bears some analogy to the effects more commonly observed in beams of light admitted into dark spaces, and sometimes designated by the term diffraction.

Sect. IV.—*Of Periodical Colours in general.*

By far the greater part of the phenomena of colours, except their separation by simple refraction, are referrible to the description of periodical or recurrent colours; being characterized by an alternation which is generally repeated, where the observation is sufficiently extensive, several times in succession, while the circumstances on which they depend are varied uniformly and by slow degrees. The number of these alternations, when light perfectly homogeneous is employed, appears to be continued without any discoverable limit, although it is always smaller, for any given change of circumstances, when the least refrangible or red light is employed, than when the observation is made on the most refrangible or violet; so that mixed or white light always produces a combination of alternations arranged according to a series of different intervals, which are at first more or less distinct, but by degrees are so mixed with each other as again to be lost in the general effect of white light. In all these cases the appearances may be reduced to calculation by means of the general law of the interference of two portions of light, with its appropriate modifications and corrections.

A. *The law is, that when two equal portions of light, in circumstances exactly similar, have been separated and coincide again in nearly the same direction, they will either cooperate or destroy each other, according as the difference of the times occupied in their separate paths is an even or an odd multiple of a certain half interval, which is different for the different colours, but constant for the same kind of light.*

B. *In the application of this law to different mediums, the velocity must be supposed to be inversely as the refractive density.*

C. *In reflections at the surface of a rarer medium, and of some metals, in all very oblique reflections, in diffraction, and in some extraordinary refractions, a half interval appears to be lost.*

D. *It is said that, according to some late observations of Mr Arago, two portions of light, polarised in transverse directions, do not interfere with each other.*

E. *The principal intervals in air are, for the*

Extreme Red...........	·0000266 = $\frac{1}{37640}$
Yellow....................	·0000235 = $\frac{1}{42550}$

Sect. V.—*Of the Colours of Thin Plates.*

The colours exhibited by very thin plates of transparent or semitransparent substances have been well known to optical philosophers, from the time that they were first noticed by Boyle, and more particularly examined by Hooke and Newton. They may be readily observed by pressing together any two clean pieces of common plate-glass, which have always sufficient convexities and concavities to exhibit them, touching each other in some points, and leaving elsewhere a thin plate of air between them; or, still more conveniently, by selecting from the plano-convex lenses, kept by the opticians, such as have their flatter sides very slightly convex, and are consequently calculated to throw the spaces of equal thickness, and the colours dependent on them, into the form of rings. The colours are most distinct when they are formed in the light reflected from the two surfaces in contact, especially when care is taken to exclude the foreign light reflected by the surfaces not concerned in their production; and in this case they begin from a central dark spot, immediately surrounded by a bright light, and then by rings more distinctly coloured, while the colours, exhibited in light transmitted through the glasses, begin from a bright spot in the centre, surrounded by a dark ring, being always exactly complementary to the colours seen by reflection, to which they are also, as Mr Arago has demonstrated, either exactly or very nearly equal in intensity, although they have generally been supposed to be much less vivid, on account of the diminution of their effect on the eye by their mixture with the whole of the beam of light which affords them. But if we employ for the observation two flattish pieces of glass, held in such a position as to transmit the light received from one part, and to reflect an image of another part, of an object equally illuminated throughout its extent, the two series of colours will destroy each other, and the whole appearance of rings will vanish. When, on the contrary, the illumination of the object varies materially, the rings will re-appear in one or other of their forms, according to the different intensities of the lights received from its different parts; so that, as Mr Arago has ingeniously suggested, this test might be employed to answer the purpose of a photometer, for ascertaining the equality of the lights of two distant objects.

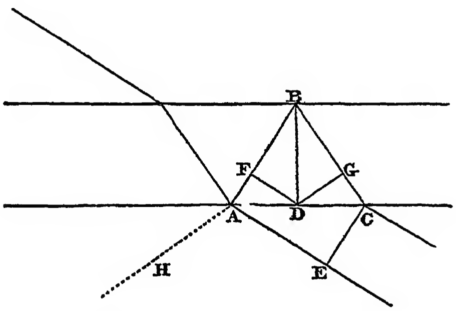
If any thin plate affording colours be inclined to the direction of the light passing through it, the appearance of the colours will be changed either precisely or very nearly in the same manner as if the thickness were reduced in the ratio of the radius to the cosine of the inclination within the plate; at least, if this proportion is not perfectly accurate, the deviations from it, in the experiments of Newton, are manifestly within the limits of the unavoidable errors of observation.

We are indebted to Mr Arago for the important fact, that the colours observed in transmitted light are distinguished by a polarisation opposite or transverse to that which is appropriate to transmitted light in general, and possessing the ordinary character of the polarisation produced by partial reflection. It is in light thus reflected that we must seek for one of the two portions which are to be combined according to the laws of interference, in the case of the colours seen by transmission, and for both in the case of reflection. The light transmitted simply through the plate will be followed by a portion which has been reflected back from the second surface to the first, and forwards again from the first to the second; and the difference of the times occupied in these different paths will obviously be proportional to the thickness of the plate, and also, according to the modification (B) of the law, to its refractive density; so that the number of alterations of any given colour between the central spots of the rings and any given point will be as the thickness of the plate at that point; and the numbers for different colours will

Chromatics.

be inversely as the magnitudes of the appropriate intervals; the plate appearing light when illuminated by a homogeneous colour, only where the thickness corresponds to any exact multiple of the interval, and dark at the intermediate points; and this proportion is found to agree perfectly with experiment. The two reflections within the plate being always of the same kind, will either not require any correction on account of their nature (C), or will altogether add a whole interval to the length of the path; an alteration which makes no change in the appearances.

When the incidence is oblique, the actual length of the two passages of the reflected ray across the plate AB, BC, is as twice the secant of the angle of refraction ABD, and its advance upon the surface AC, as twice the tangent; and this advance, reduced to the direction of the transmitted ray AE without the plate, must be subtracted from the retardation within the plate; the reduction being in the proportion of the radius to the sine of the angle of incidence ACE, for which, if we substitute that of the radius to the sine of the angle of refraction ADF or CDG, we



shall have the deduction required to be made from the length of the path within the plate, since the velocities vary directly as these sines; and by this deduction the secants AB, BC, will be reduced to the cosines BF, BG: so that the true retardation will always be proportional to the cosine of refraction.

The same demonstration is applicable to the difference of the paths of the two portions of light reflected once only, from the upper and lower surfaces of the plates respectively, supposing A, the point of emergence of the transmitted ray, to become the point of incidence of a new reflected ray HA. Hence it might be expected that all the phenomena of colours should be the same as in the case of transmitted light; and this really appears to happen when the observation is made on a plate of air contained between a transparent substance and a polished surface of gold or silver; or on a plate of a refractive density intermediate between the densities of the neighbouring substances, as in the instance of a thin coat of smoke or of an oxide, adhering to any polished metallic surface, which is at first of a yellowish white, and, as it becomes thicker, changes to a yellow and an orange colour; but in more common cases there is a loss of half an interval in one of the two reflections only, so that the thicknesses affording a perfect coincidence for any species of colour, are always intermediate between the thicknesses affording the same colour by transmission; and hence the tints of the two series of rings are always complementary to each other, the series seen by reflection always beginning from a dark central spot, when they are exhibited by any detached transparent substance, as a soap bubble, a thin film of glass or of talc, or by a plate of air contained between two plates of glass, or between a plate of glass and a piece of polished steel.

There is a peculiarity in the surface of silver and gold, and perhaps of some other metals, that, besides the regular reflection at an angle equal to that of incidence, a considerable quantity of light is dispersed irregularly; and this light, as Mr Arago has observed, is polarised in a direction transverse to that of the usual polarisation by reflection; there is also in the irregular reflection no loss of a half interval; so that it exhibits, with a piece of glass, a series of rings resembling those which are produced by polished steel, except that their dimensions are not varied exactly in the same proportion by the obliquity of the incidence, because the light which forms them is not required to pass towards the metal in an angle exactly equal to that which it makes upon its return after reflection; and there will probably be considerable irregularities in the interval of retardation, according to the mode of performing the experiment; although in general the irregular dispersion or diffraction from the glass is too weak to afford colours easily observable, when the position of the plate differs considerably from that in which the light is regularly reflected. If a portion of polarised light is incapable of interfering with another portion polarised in a transverse direction, these rings ought to disappear when the angle of incidence on the plate of glass is about 55°, since in this case the light reflected by it is completely polarised in the plane of incidence: and this disappearance seems actually to have been observed in some of Mr Arago's experiments, though in others, where the metallic surface was less highly polished, the polarisation of the dispersed light may have been less complete, and the rings may still have been visible at this angle. (*Mémoires d'Arcueil*, vol. iii. p. 354, 359.)

Sect. VI.—*Of the Colours of Double Plates.*

When light is transmitted in succession through two plates, differing but little in thickness, they exhibit an appearance of colour similar to that which would be produced by a single plate equal in thickness to their difference; and this appearance is wholly independent of the distance of the plates from each other. It was first noticed by Mr Nicholson in the glasses employed for the sights of sextants, and is attributed by Dr Young to "the rays twice reflected in the second only." In some circumstances, however, the light returning from the second glass to the first, and again reflected by it, may co-operate in the effect, the interval of retardation being the same in both cases. Mr Knox has more lately described some very striking appearances of colours, obtained in this way, by the combination of two pairs of lenses, each exhibiting their appropriate rings when viewed separately, and affording together a third series of rings of larger dimensions when the two former are unequal in magnitude, and of straight bands when they are equal. It is in fact easily demonstrable, that in order that the thicknesses of the plates of air, contained between two unequal pairs of lenses, may be equal, the distances from the centres of contact must be in a constant proportion; and it is well known that all the points from which the lines drawn to two given points are in a constant proportion, will be found in the circumference of a circle, the diameter of which is a third proportional to the difference and sum of the segments of the given distance of the points: so that the colours, depending on this difference, instead of beginning as usual from a white central spot, will begin from a white ring, and will be arranged in concentric rings on each side of it, precisely in the same order as when they form concentric rings round an actual point of contact; and when the curvatures of the two pairs of lenses are equal, the diameter of the circle becoming infinite, it will obviously be converted into a right line.

Dr Brewster has observed a series of similar phenomena

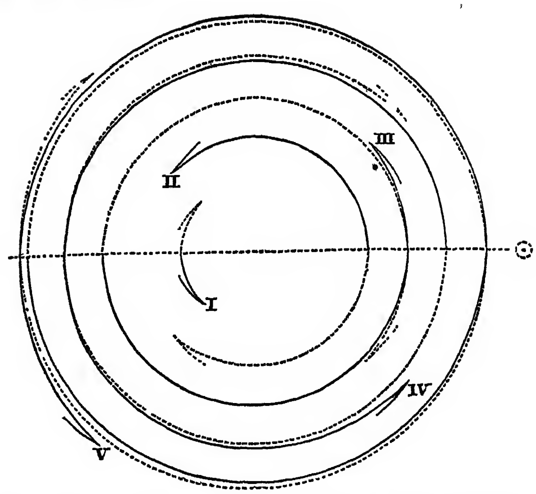
produced by two plates, of equal thickness, but forming a small angle with each other, so as to be differently inclined to the light passing through them. The effect of the inclination being to reduce the virtual thickness of the plate in the ratio of the cosine, and the difference of the cosines of equi-different arcs being simply as the sine of their half sum, it is evident that the colours must correspond to a thickness which varies nearly as the sine of the angle of incidence, considered with regard to a plane bisecting the angle formed by the plates; and this result agrees correctly with Dr Brewster's experiments.

Sect. VII.—*Of the Colours of Supernumerary Rainbows and Glories.*

Within the common primary rainbow, and without the secondary, we sometimes observe a partial repetition of colours, more or less distinctly marked, and extending occasionally to several alternations; the repetitions occupying somewhat narrower spaces, as they are more remote from the ordinary bows. These appearances seem to have been first described by Mariotte; they have been since noticed by Langwith, Daval, and Dicquemare; and the term supernumerary rainbows has been very properly applied to them. The coloured circles called glories may generally be seen surrounding the shadows of our heads when we have an opportunity of standing on a high hill, and observing them in a cloud below us; they are also sometimes accompanied by a large white circle, which, in an observation of Ulloa, was 67° in diameter; and such a circle may frequently be distinguished when the sun shines on a mass of vapour rising from a warm bath, of nearly the same dimensions, or sometimes a little smaller. The whole of these phenomena may be explained, from the interference of some of the portions of light regularly reflected within the minute drops of water, with other portions, incident at a different angle, but, after an equal number of reflections, coinciding ultimately with them in direction; supposing only the clouds in question to afford a number of these drops, varying but little from each other in diameter. We find, by the well-known mode of calculating the greatest deviation, that each order of reflections exhibits a zone from 30° to 10° in breadth, through which a double light is diffused by each drop; and, besides this, when there have been more than three reflections, the portions belonging to the opposite sides cross each other in one or more points, and surround the drop, or rather the observer, if we consider the effect of the refraction of a multitude of drops situated in all directions. Supposing the index of refraction for the extreme rays 1·336, and its logarithm ·1258000, the results will be these:—

After	Extreme Deviation.	Final Deviation.
1 reflection	41° 40′	13° 52′
2	51 41	69 12
3	40 39	27 44
4	45 2	55 20
5	50 0	41 36
6	34 14	41 28

We may obtain a more distinct idea of these duplicatures if we represent them in a diagram, showing the angular extent of the diffusion of light derived from each order of reflections, and distinguishing by different kinds of lines the portions belonging to the opposite halves of the drops; and it will be obvious, from the inspection of this figure, that the appearances in question have only been observed within some of the duplicatures of the orders to which they belong, between the angles of extreme and of final deviation. The tertiary and quaternary bows (III. IV.) are evidently too near the luminary to be visible; the



quinary (V.) ought to be seen in the space between the primary and secondary; but it is probably much too faint to be visible under any circumstances. The duplicature belonging to the primary rainbow exhibits two portions, for which we may calculate the interval of retardation in parts of the radius of the drop, supposing the velocity to be that which is appropriate to the air, by taking twice the difference of the cosines of incidence on the drop, and multiplying twice that of the cosine of refraction by the index 1·336; the difference of these differences giving the interval for the two portions, of which the direction has been found to coincide by a previous calculation.

Distance from the Edge.	Angle of Reflection.	Difference of the Paths.
0°	40° 2′	·0000
1	42 59 / 36 23	·0014
2	44 2 / 34 32	·0040
3	44 45 / 33 3	·0074
4	45 20 / 31 45	·0113
5	45 46 / 30 34	·0160
6	46 9 / 29 26	·0210
8	46 45 / 27 20	·0327
10	47 12 / 25 24	·0461
12	47 32 / 23 33	·0612

Hence it may be inferred, that, supposing the extreme red to re-appear at the distance of 2° from the primitive external termination of the rainbow, the radius of the drop must be $\frac{\cdot 0000266}{\cdot 004} = \cdot 00665$, or $\frac{1}{150}$ of an inch; the fourth alternation of the red being at the distance of 5°, where the interval is ·016. The magnitude of the interval, at an equal distance from the edge, varies but little with the refractive density: thus, for violet light, the index of refraction being probably about 1·346, and its logarithm ·1290000, the greatest deviation will be found 40° 14′; and for a deviation 2° less, the angles of refraction must be 43° 30′ and 33° 37′, and the interval will be little different from ·00400.

The supernumerary bands of the secondary bow, formed by the same drops, will be a little broader than these, since it appears, from a similar calculation, that the rays inter-

fering with each other, at the distance of a degree from the edge, will exhibit an interval of ·0011 of the radius only, instead of ·0014.

The supernumerary colours of the third and fourth bows will be equally imperceptible with the bows themselves; but the portions of light, four times reflected, will cross each other in the point opposite to the sun, where their coincidence will be perfect, and at other neighbouring points will afford an interval nearly proportional to the distance from that point. We shall find that the intervals for different deviations, supposed to be measured in air, are these:—

Deviation.	Angle of Reflection.	Interval in parts of the Radius.
180°	24° 49′	·000
185	25 31	·096
175	24 7

Hence, supposing the first bright or greenish ring to appear at the distance of 5° from the observer's head, the radius of the drops must be about $\frac{\cdot 0000225}{\cdot 096} = \cdot 000234$, or $\frac{1}{4370}$ of an inch.

It might be questioned whether the light, five times reflected, could retain sufficient force to produce any sensible effects by these interferences; but since it exhibits no appearance of colour between the primary and secondary rainbows, it must necessarily be extremely faint. The interval which it affords, by the comparison of its two portions, agrees sufficiently well with that which is derived from four reflections, to contribute in some measure to the production of an alternation of light and shade; but the separate colours would be rather weakened than strengthened by the mixture: thus, at the deviation of 5°, the interval is found to become ·076 instead of ·096; and at 10°, ·155 instead of ·195; and this difference is too considerable to allow us to expect any material increase of brilliancy from the addition of the fifth reflection, however great its intensity might be.

Supposing, now, a cloud to consist of spherules of which the radius is ·000234, we may inquire at what distance from the outer edge of the primary rainbow the first additional red of the supernumerary colours ought to be found: the interval being in parts of the radius $\frac{\cdot 0000266}{\cdot 000234} = 116$; and we may infer from the table, by taking the successive differences, that this distance will be about 18°; so that the semidiameter of this red ring will be 42 — 18 = 24°; and the termination of the primitive band of red, supposing it to extend to one fourth of a complete interval only, will be where the difference is ·029, or at $7\frac{1}{2}$°; but for the violet the quarter of the interval will be, in parts of the radius, $\frac{\cdot 0000042}{\cdot 000234} = \cdot 0183$, which answers to a distance from the edge of about $5\frac{1}{2}$°; and this distance, measured from the edge of the violet, which is somewhat less than 2° within that of the red, will extend nearly to the same point as the red space; so that we shall have a circle about 70° in diameter, at the circumference of which all the colours will be united, and which will consequently be white. This magnitude agrees tolerably well with the direct observations of the phenomenon; and if we wish to make the agreement more complete, we have only to suppose the drops a little smaller, and the coloured glories, which they are capable of affording, a little larger. It has already been remarked, that the non-appearance of the ordinary rainbow, in this case, must be referred to the operation of something like diffraction; although it is obvious that its form, under such circumstances, would necessarily be somewhat modified by the diffusion of the colours through a greater space than that which they ordinarily occupy.

Sect. VIII.—*Of the Colours of Striated Substances.*

It was observed by Boyle that small scratches of any kind on the surfaces of polished substances exhibited, when viewed in the sunshine, a variety of changeable colours; and the observation may easily be repeated with any piece of metal not too highly polished, and placed in a strong but limited light. Dr Young ascertained by experiment that the colours afforded by some regular lines drawn on glass always corresponded to an interval, varying as the sine of the angle of deviation from the position in which an image of the luminous object was exhibited by the regular reflection of the surface; and it is easily shown, that if we suppose two portions of light to be reflected from the opposite edges of the furrow, the difference of their paths must vary in that proportion. Dr Young had conjectured that the colours of the integuments of some of the coleopterous insects might be derived from furrows of this nature; but the conjecture has not been verified by observation. Dr Brewster has, however, very unexpectedly discovered that some similar inequalities are the cause of the colours exhibited by mother of pearl; and he has confirmed the observation by showing that impressions of the surface of this substance taken in black wax, in a hard cement, or in fusible metal, will often exhibit a similar appearance. Where the form of the surface of the mother of pearl is the most regular, it reflects, in an oblique light, a white image of a luminous object, like that which any other polished substance affords; but on one side of this image only, and at some little distance from it, we may observe the first order of recurrent colours, beginning from violet, and occasioned in all probability by the reflections from one side only of an infinite number of parallel striæ, formed by the terminations of a minute lamellated structure, nearly but not perfectly perpendicular to the general surface; one side only of each of the little furrows being situated in such a direction as to reflect an image of the luminous object to the eye, and at such a distance that the whole may constitute a regular series of equal intervals. By transmitted light, this substance generally appears of a red or a green colour, changing more or less according to the obliquity, and apparently belonging to some of the higher orders of recurrent colours.

Dr Young has observed a series of these colours, produced by the parallel lines of some of Coventry's glass micrometers, drawn at the distance of $\frac{1}{500}$ of an inch from each other, in which the first bright space, or the confine between the green and the red, corresponded to the interval of $\frac{1}{43000}$ of an inch, or ·0000232 (*Medical Literature*, p. 559); and this result agrees very accurately with the general theory, the interval for the yellow, derived from Newton's measurements, being ·0000235; but in general these lines exhibit colours much more widely extended, each separate line consisting in reality of two or more scratches at a minute distance from each other.

There is a remarkable peculiarity in the appearance both of these colours, and of those which are exhibited by substances naturally striated, as by mother of pearl, agate, and some other semitransparent stones; they lose the mixed character of periodical colours, and resemble much more the ordinary prismatic spectrum, with intervals completely dark interposed. This circumstance may be satisfactorily deduced from the general law, if we consider that each interference depends not only on two por-

tions separated by a simple interval, but also on a number of other neighbouring portions, separated by other intervals which are its multiples; so that unless the difference of the two paths agrees very exactly with the interval appropriate to each ray, the excess or defect being multiplied in the repetitions, the colour will disappear; consequently each of the stripes, which in other cases divide the space in which they appear almost equally between light and darkness, when homogeneous light is employed, becomes here a narrow line; and their succession affords a spectrum exhibiting very little mixture of the neighbouring colours with each other, and nearly resembling that which is afforded by the simple dispersion of the prism; except that, as in all other phenomena of periodical colours, the blue and violet portions are much more contracted than in the common spectrum.

Sect. IX.—*Of the Colours of Mirrors, and of thick Plates.*

In all the species of periodical colours which have been described, the two portions of light concerned have both been regularly reflected from different surfaces. The methodical division of the subject now leads us to the consideration of the colours exhibited in light separately reflected from the same surface. These may be denominated in general the colours of mirrors; and they will include as a variety those which are called by Newton the colours of thick plates.

The general character of these colours is, that they are observed in light reflected by small particles, or irregularly dissipated by a single surface, first in the passage of the beam of light towards the mirror, and then in its return; the difference of the length of their paths affording, as usual, the interval of retardation. Thus, in Dr Herschel's experiment of scattering a fine powder in a beam of light reflected perpendicularly by a concave mirror, and received on a screen in its return, it may easily be shown that the colours will be precisely such as would be exhibited by light transmitted through a thin plate of air, everywhere half as thick as the plate limited by two spherical surfaces in contact; the centre of the one surface being the particle of powder, and that of the other its image formed by the mirror. For in the direction of the principal ray, which is perpendicular to the mirror, the paths of the light will be of equal length, whether the dissipation takes place before or after the reflection; and in other parts the whole length of the path of the light passing from any local point to its conjugate focus being the same, according to the definition of a conjugate focus in the Huygenian theory, from whatever point of the mirror it may be reflected, the light first dissipated will have advanced, after its reflection, as far as the circumference of a circle, of which the conjugate focus is the centre, at the same instant that the portion coming directly from the powder, after a previous reflection, will reach the circumference of the circle of which the particle of powder is the centre; so that the distance between these two circles must be the difference of the paths of the two portions, and the colours the same as would be exhibited by a plate of air of half the thickness, since such a plate is twice traversed by the retarded light.

A similar appearance of colours had been obtained, by earlier experimenters, from the interposition of a screen of gauze, or of a semitransparent substance, in the path of the beam falling on the mirror. But the colours of thick plates, observed by Newton, are modified by the nature of the transparent substance employed, and by the obliquity of the refracted light. The dissipation here takes place at the anterior surface of a concave mirror of glass, and the reflection at the posterior, which is coated with quicksilver: and if these two portions proceed, each with a slight divergence, from a perforation in a screen situated near the centre of curvature of the mirror, they will co-operate perfectly with each other in the circumference of a circle described on the screen, of which the diameter is the distance of the perforation from its image; since all the light passing, in any given section of the mirror, with the same obliquity through the glass as the beam itself passes in the principal section, must be collected into a focal point situated in some part of this circle, and will arrive at this point at the same time, whatever its situation in the section may have been; the obliquity of the incident light being the same in every part of the section, because the point of divergence is at the same distance from the mirror as the centre of curvature. For the other parts of the dissipated light, passing with different obliquities, the interval will be determined by the difference between the lengths of the paths of the two portions of light arriving at the given point, the one by regular refraction, after being first dissipated and then reflected; the other by dissipation, after being first regularly refracted and reflected. And this interval agrees precisely with the law which Newton has deduced from his experiments, but the analogy which he infers from it, between these colours and those of thin plates, is in fact very far from amounting to identity; since, if they belonged to the ordinary colours of thin plates, there is no reason why the series should begin anew from a certain arbitrary thickness, differing in every different experiment, which affords a white of the first order.

Sect. X.—*Of the Colours of deflected Light.*

We are next to examine the case of light only once reflected, and interfering with a portion of the same beam which has pursued its course without interruption; a case which would scarcely have required a separate consideration, but from the difficulty of including it in a general definition with any others; although it is comprehended in the Newtonian description of the colours of inflected light: but since the light is in this case turned away from the substance near which it passes, it may more properly be termed deflected, especially as the greater number of the appearances mentioned by Newton as depending on inflection, belong more properly to diffraction, and the term inflection might consequently be misunderstood as relating to them.

When a beam of light is received in a dark room, and suffered to fall upon the edges of two extremely sharp knives or razors, meeting each other in a very acute angle, the shadows of the knives, received on a screen at some distance, will be found to be bordered by several fringes of colours; and the angle will be bisected by a dark line. The distances from the shadows at which these fringes appear agree in general with the supposition of their depending on the interference of the light reflected from the edges of the respective knives, with the uninterrupted light of the beam passing between them; but the coincidence of these portions ought to be perfect in the immediate neighbourhood of the point in which the shadows meet, and the two last bright fringes ought to unite there in an angle of light. This, however, does not happen, on account of the modification of the general law (C), which makes it necessary to allow half an interval for the effect of a very oblique reflection; and for the same reason, the space immediately next to the shadow is always dark instead of being light. If the knives are at all blunt, the reflection from one to the other, where they meet, causes the bisecting dark line to disappear; but this source of error may be avoided by causing one of them to advance a little before the plane of the other.

Mr Fresnel has repeated these experiments with all possible care, and has ascertained that the points in which the fringes of any one colour are found, at different distances from their origin, belong always to a hyperbola, as they ought to do according to the calculation founded on the general law of interference; a fact which had before been inferred from other measurements, but which had not been so distinctly proved by direct experiments. Newton himself, indeed, was so far from believing that these fringes are rectilinear, as Mr Fresnel supposes, that he expressly mentions their curvature, and infers from it that they are not derived from "the same light" in all their parts; imagining, perhaps, that each fringe was of the nature of a caustic line, formed by reflection or refraction, in which the light is everywhere more condensed than in the collateral spaces, but which is by no means necessarily straight. Mr Fresnel has also shown that all the fringes are found exactly at such distances from the true shadow, as would be inferred from the supposition of the loss of half an interval by reflection; while some of the experiments of Newton appeared to indicate a deviation from this law. It has been asserted that fringes of the same kind have been observed at the edges of a detached beam of light, reflected into a dark space by a narrow plane and polished surface; and in this case it would be difficult to point out in what manner the supposed oblique reflection could be produced, or how a diffraction of any kind could cause the light to be redoubled back upon itself; but the experiment does not appear to have been hitherto performed with sufficient attention to all possible sources of error.

SECT. XI.—*Of the Colours of diffracted Light; including those of Fibres and of Coronæ.*

The light reflected from each of the knife edges, in experiments like those of Newton, not only produces colours by its interference with the light proceeding uninterruptedly between them, but also with another portion, diverging from the edge of the opposite knife, and spreading into its shadow. This tendency of light to diffuse itself was first described by Grimaldi, under the appropriate name diffraction; but many of the phenomena in which it is concerned having been attributed by Newton to other causes, he appears almost to have overlooked its existence.

The general law of interference is very directly applicable to all phenomena of this kind; the fringes exhibited are broader in the same proportion as the distance between the edges is narrower; and they always depend on the difference of the distance from the edges as the interval of retardation. It is, however, necessary to suppose the same modification to take place in diffraction as in oblique reflection, half an interval being lost in both cases; since the light which deviates the least from a rectilinear direction, and which is derived from the near approach of the two paths to equality, is always white. But it is remarkable, that when the obliquity becomes a very little greater, the diffracted light seems to change its character in this respect; for the colours occupy the same spaces as would have belonged to them if they had begun from a dark centre, one of the portions only having lost a half interval in comparison with the other; and of this circumstance no explanation has yet been attempted.

The diffraction producing these fringes may easily be detected within the eye itself, by holding any object near it in such a position as to intercept nearly all the light of a candle except a narrow line at the edge: this line will then appear to be accompanied by other lines parallel to it, separated from it by a dark space, and becoming wider when the object is brought nearer to the eye. These fringes must be referred to the light diffracted on one side round the object, so as to be spread on the unenlightened part of the retina, and reflected on the other from the margin of the pupil; for if we employ an object narrower than the pupil, so as to observe them on both sides of it, their magnitude will be altered by any change in the aperture of the pupil, occasioned by admitting light to the opposite eye, or otherwise. In such cases as this, where one of the points of divergence is much nearer to the point of interference than the other, the interval increases more rapidly than the distance from the primitive direction; and the first fringes are much broader than those which succeed them; the mode of their formation approaching to that of the fringes seen in deflected light, commonly called the exterior fringes of the shadow; while the interior fringes belong more immediately to the present subject, that of the colours of diffracted light.

When the distance of the points of divergence is more nearly equal, the one being collateral to the other, the breadth of the successive fringes is also more uniform. Such is the appearance of the colours exhibited by a number of equal fibres held between the eye and a distant luminous object; their origin being identical with those of the fringes produced in the shadows of the knives, except that the diffracted rays come from the remoter side of the fibres, and follow the reflected rays instead of preceding them. These colours may easily be observed by looking at a candle through a lock of fine wool, and still more distinctly by substituting for the wool some of the seeds of the lycopodium, strewed on a piece of glass; and they become very large if we employ a few of the particles of the blood, or the dust of the lycoperdon, or puff ball. Dr Young has made this appearance the foundation of a mode of measuring the fineness of wool, which he has recommended for agricultural purposes, though it seems hitherto to have been found much too delicate to be employed by "the hard hands of peasants" with any advantage. The instrument which he has invented for this examination is called the eriometer, and its scale is calculated to express, in semidiameters of a circle, formed round a central aperture in a card or a plate of brass, and marked by minute perforations, the distance at which the lock of wool must be held, in order that the first bright ring of colours, or the limit of the green and the red surrounding it, may coincide with the circle of points; and the actual measure, expressed by a unit of this scale, is found to agree very nearly with the thirty thousandth of an inch. Thus the particles of water which have been found capable of exhibiting a glory 5° from the shadow of the observer, being about $\frac{1}{2185}$ of an inch in diameter, they would correspond to number fourteen of this scale; and the cotangent of the angle subtended by the semidiameter of the bright circle being fourteen, the angle itself will be about 4°; consequently, if we looked at the sun through such a cloud, he would appear to be surrounded by a bright circle of colours, 8° in diameter, green within and red without, and attended by other colours, more or less distinctly marked, according to the degree of uniformity of the magnitude of the drops. These circles are called coronæ: their dimensions vary considerably, but they have seldom been observed quite so large as these drops would make them; and more commonly they seem to depend on drops about a thousandth of an inch in diameter, although it is not easy to ascertain the precise parts of the rings from which the measures have been taken by different observers.

In the shadow of a larger substance, formed in a beam of light admitted into a dark room, these colours are still perceptible, beginning from a white line in the middle; but here both the portions on which they depend are diffracted into the shadow, and beyond its limits they are lost in the stronger light that passes on each side of

it. Their appearance is somewhat modified when the shadow is formed by a body terminating in an angle; for the breadth of the fringes being inversely as the breadth of the object which forms them, it is obvious that this breadth must increase towards the point of the shadow, like the distance of the fringes formed in the shadows of Newton's knives: and the fringes seen within the angle must necessarily assume the character of hyperbolas; nor will this form be materially altered when the angle becomes a right one, as in the crested fringes noticed by Grimaldi, although the steps of the calculation for determining their magnitude are in this case a little more complicated.

We find, in an elegant experiment of Mr Biot, on the fringes produced by diffraction, a singular confirmation of the truth of the theory which derives these colours from the difference of the times occupied in the passage of the different portions of light to the point of interference; although this celebrated author does not seem to have been aware of the nature of the inference which may so naturally be drawn from it. He found that the densities of the substances, from the margin of which the diffracted light originated, had no influence whatever on the appearances produced by them; but when they were formed in the light diffracted from substances placed at one end of a long tube, and observed on a piece of glass fixed at the other end, they became contracted, upon filling the tube with water, in the proportion of four to three; as was to be expected from the diminished velocity which must be attributed, according to the modification of the general law (B), to the passage of the light through a denser medium.

Sect. XII.—*Of the Colours of Mixed Plates.*

The colours of mixed plates depend partly on diffraction, and partly either on reflection or on direct transmission; but their essential character consists in the different nature of the two mediums through which the light passes after its separation.

When a minute quantity of moisture is interposed between two lenses, it readily divides itself into a great number of smaller portions, scarcely distinguishable by the eye; and the light transmitted through the lenses exhibits rings of colours much larger than those which are ordinarily observed, and depending on the interval afforded by the difference of the velocities in the different mediums, according to the inverse proportion of the refractive densities. If they are viewed in a direct and unconfined light, the rings belong to the series commonly seen by transmission, beginning from a light central spot; both portions passing in this case simply through the separate mediums, and arriving at the eye after some slight diffraction only, which affects both of them in an equal degree; but if a distant dark object is situated immediately behind the lenses, and they are illuminated by a light incident a little obliquely, their character is changed, and they resemble the colours commonly seen by reflection, one of the portions of light being necessarily reflected, as in the case of the colours of deflected light; so that, when the dark object is situated behind one half of the glasses only, we observe the halves of two sets of rings, of opposite characters, exhibiting everywhere tints complementary to each other. The diameters of the rings vary according to the refractive density of the liquid employed, diminishing as that density increases, and becoming much larger when two liquids, incapable of mixing with each other, and differing but little in refractive density, as oil and water, are employed instead of air and a single liquid.

The magnitude of the interval may also depend on that of a minute transparent solid substance, immersed in a liquid, instead of being limited by the distance of the two lenses; thus the dust of the lycoperdon, mixed with water, gives it a purplish hue when seen by indirect, and a greenish by direct light; and when salt is added to the water, or oil is substituted for it, the difference of the velocities being lessened, the colours exhibited rise in the series, as if the plate were made thinner.

Mr Arago has very ingeniously applied the principle of the production of these colours to the construction of an instrument for measuring the refractive densities of different elastic fluids, and of air in different states of humidity; the fluids being contained in two contiguous tubes of a given length, through which the two portions of light are made to pass, previously to their re-union, and to the formation of the bands of colours; and it may easily be conceived, that the delicacy of such a test must be great enough for every determination that can be required, either for the correction of astronomical observations, or for the illustration of the optical properties of chemical compounds.

Sect. XIII.—*Of the Laws of the Polarisation of Light.*

The colours first observed by Mr Arago in doubly refracting crystals, and since more particularly analysed by Mr Biot, afford by far the most striking and interesting examples of the colours of mixed plates. In order to understand the laws of these phenomena, it is necessary to be previously acquainted with the affections of polarised light, which were first accurately investigated by Malus, and with the theory of extraordinary refraction, derived by Huygens, with equal elegance and precision, from his peculiar hypothesis respecting the nature of the transmission of light.

1. Mr Malus discovered, that at a certain angle of incidence, the light partially reflected by a transparent substance receives a peculiar modification, with respect to the plane of reflection, which is called *polarisation in that plane.*

2. Dr Brewster observed, that the *angle of complete* polarisation is such, that the mean direction of the transmitted light is perpendicular to that of the reflected portion; the tangent of the angle of incidence being equal to the index of the refractive density of the medium.

3. A ray of polarised light is again subdivided, in the usual proportion, by a second refraction in the plane of polarisation; but when it is refracted in a *plane perpendicular* to the plane of polarisation, by a surface properly inclined, *there is no partial reflection;* and in intermediate positions, the intensity of the reflection is nearly as the *square of the cosine* of the angular distance of the two planes.

4. A portion of the *transmitted* light is polarised in a *direction perpendicular* to that of the plane of refraction; so that none of this portion is reflected by a second surface parallel to the first; and when there are several parallel surfaces in succession, the whole of the transmitted light becomes at last so polarised, that none of it is partially reflected.

5. The same transverse polarisation will happen in a *greater number* of transmissions, when the *angle differs* from that of complete polarisation; and in the same manner a second partial reflection, by a surface parallel to the first, will produce a more complete polarisation, when the first is imperfect.

6. A perfect polarisation in any new plane, by a partial reflection at the appropriate angle, completely *supersedes* the former polarisation; but a reflection or refraction void of any polarising effect, which may be called a *neutral* reflection or refraction, changes the direction of the plane of polarisation, according to Mr Biot's experiments, into that

of the image of the former plane, supposed to be formed by the action of the given surface.

7. The light *ordinarily refracted* by a doubling crystal in the plane of the principal section of the crystal, passing through its axis, is *polarised in that direction;* the light *extraordinarily* refracted, in the *transverse direction.*

8. Light *previously polarised* is transmitted by the ordinary refraction when its plane of polarisation coincides with the principal section, and by the extraordinary when it is perpendicular to it. In intermediate directions, the quantity of light transmitted by each refraction is, according to Malus, as the square of the cosine and sine of the angle formed by the planes passing through the paths of the ray, and a line parallel to the axis in each crystal, supposing the species of refraction to be exchanged.

9. The rays of light ordinarily transmitted by doubling crystals appear in general to *retain their previous polarisation,* like rays transmitted through simple substances; but the extraordinary refraction polarises them, according to Biot, like a neutral reflection at a surface coinciding with the principal section; the new plane of polarisation taking the place of the image of the former.

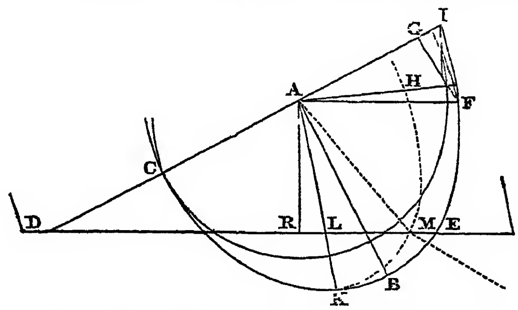
10. Reflections at *metallic surfaces* are generally neutral with respect to polarisation; but in oblique planes they seem, according to some experiments of Malus, to mix or depolarise the light subjected to them.

Sect. XIV.—*Of the Laws of Extraordinary Refraction.*

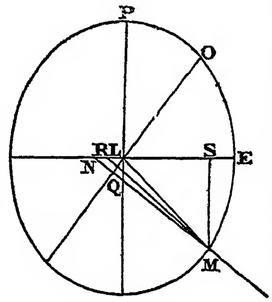
The extraordinary refraction of regular doubling crystals may be correctly determined in all circumstances, by means of the Huygenian supposition of an undulation diverging in the form of a spheroid from every point of the medium, the velocity in any given direction being always proportional to the corresponding diameter, so that the successive spheroidal surfaces remain always similar to each other. The relations of the angles of incidence and refraction may be calculated by finding the point in which any of the spheroids, supposed to represent the forms of the elementary undulations, at a given instant, is touched by a plane passing through that point of the surface at which the original beam of light would have arrived, at the same instant, through the external medium; it may also be deduced, somewhat more simply, from the determination of the velocity with which an expanding spheroidal undulation must extend itself on any given surface; a velocity which immediately gives us the direction of the ray in the surrounding medium; and the relation thus obtained will also obviously hold good with respect to a ray returning in the opposite direction. (*Quarterly Review*, No. xxi.)

In common refractions, if we compare the space described by an undulation or any given surface with the radius, the velocities appropriate to the different mediums will be represented by the sines of the respective angles; but the velocity with which a spheroidal undulation advances on any surface is evidently determined by the increment, or the fluxion, of the perpendicular to the circumference of the section of the spheroid formed by that surface; and calling this perpendicular y, the velocity may be considered as proportional to its increment y': but the velocity of the surrounding medium is to that with which the axis x increases, as r to 1, r being the index of the ordinary refractive density of the crystal, compared with that of the surrounding medium, since the velocity in the direction of the axis is the same as that which belongs to the ordinary refractive density; consequently, the increment of the path of the undulation in the surrounding medium will be expressed by rx', and s, the sine of refraction or incidence without the crystal, will be to the radius as rx' to y', and will be expressed by $\frac{rx}{y'}$, or by $r\frac{dx}{dy}$, the evanescent increments of any quantities being always in the ratio of their fluxions: and the plane of refraction or incidence, without the crystal, will always be perpendicular to the tangent of the section formed by the refracting surface. The determination of the relation of the angles is therefore reduced to the calculation of the value of y and of its fluxion.

Supposing, then, the ratio of the greatest and least refractive densities of the crystal or of the equatorial dia-



meter of the spheroid 2AB to the axis 2AC to be that of n to 1, n being greater than unity, and the tangent of the angle ADE, formed by the axis with the refracting surface DE, being called p; the magnitude of the semidiameter AF, parallel to the surface, may be found by comparing the secants of the angles FAG, HAG, subtended at the centre by the corresponding ordinates of the ellipsis and the inscribed circle: for their tangents FG, HG, being represented by p and $\frac{p}{n}$, the secants will be



$\sqrt{(1+p^2)}$, and $\sqrt{\left(1+\frac{pp}{nn}\right)}$; and the semidiameter of the circle AH being x, that of the ellipsis, AF, will be $n\sqrt{\frac{1+pp}{nn+pp}}\,x$. But the tangent of the angle GIF, made by the tangent of the ellipsis with the axis, is to that of the angle made by the corresponding tangent of the circle, GIH or GHA, that is, $\frac{n}{p}$, as n to 1; consequently $\frac{nn}{p}$ will be the tangent of the angle made with the axis by the elliptic tangent IF or by the conjugate diameter AK; and if we substitute $\frac{nn}{p}$ for p, we shall find the length of this diameter $AK=\sqrt{\frac{n^4+p^2}{nn+pp}}\,x$, which is to that of the former AF in the ratio of $n\frac{\sqrt{(n^4+p^2)}}{\sqrt{(1+pp)}}$ to 1. Hence, for the lesser semiaxis of the section formed by the given surface EL, calling AL the distance of its centre from that of the spheroid z, we have the mean proportional between the segments of the diameter $\sqrt{([AK+AL]\cdot[AK-AL])}=\sqrt{(AK^2-AL^2)}=\sqrt{\left(\frac{n^4+p^2}{nn+pp}x^2z^2\right)}$, which must be reduced in the ratio of the conjugate diameters AK and AF, so that it becomes

$$n\sqrt{\left(\frac{1+pp}{nn+pp}x^2-\frac{1+pp}{n^4+p^2}z^2\right)}=\text{EL}.$$

But from the known similarity of the parallel sections of a spheroid, the axes will be to each other as the semidiameter $\text{AF}=n\sqrt{\frac{1+pp}{nn+pp}}x$ is to nx the equatorial semidiameter, a ratio which may be called that of 1 to m, m being $=\sqrt{\frac{nn+pp}{1+pp}}$; so that the lesser axis EL being $=n\sqrt{\left(\frac{xx}{mm}-\frac{1+pp}{n^4+p^2}z^2\right)}$, the greater LP will be

$$n\sqrt{\left(x^2-\frac{1+pp}{n^4+p^2}m^2z^2\right)}.$$

Now, if q be the cotangent of the angle MNE, formed by the plane of the ray's motion in the external medium, with the lesser axis of the section, or the tangent of the angle ELO formed by the conjugate semidiameter LO with the same axis, this semidiameter may be found by substituting q for p, m for n, and the value of the semiaxis of the section for x, in the expression for AF, the semidiameter parallel to the refracting surface, and it becomes $m\sqrt{\frac{1+qq}{mm+qq}}\text{EL}=n\sqrt{\frac{1+qq}{mm+qq}}\left(\frac{xx}{mm}-\frac{1+pp}{n^4+p^2}z^2\right)=\text{LO}$. Hence, since all parallelograms described about an ellipsis are equal, dividing the product of the semiaxes EL·LP by this semidiameter, we shall have the required perpendicular $y=\text{MQ}=\frac{\text{EL}\cdot\text{LP}}{\text{LO}}=\frac{\text{LP}}{m}\sqrt{\frac{mm+qq}{1+qq}}=\frac{n}{m}\sqrt{\frac{mm+qq}{1+qq}}\sqrt{\left(x^2-\frac{1+pp}{n^4+p^2}m^2z^2\right)}$. Now, in order to find the fluxion of this quantity, increasing as the spheroid increases, while the place of the centre of radiation remains unaltered, we must make z constant while x varies, and we shall have

$$dy=\frac{n}{m}\sqrt{\frac{mm+qq}{1+qq}}x\mathrm{d}x:\sqrt{\left(x^2-\frac{1+pp}{n^4+p^2}m^2z^2\right)},$$

which must be equal to $\frac{r\mathrm{d}x}{s}$; consequently,

$\sqrt{\left(x^2-\frac{1+pp}{n^4+p^2}mz^2\right)}=\frac{ns}{mr}\sqrt{\frac{mm+qq}{1+qq}}x$; and the lesser semiaxis of the section EL, which was found $=\frac{n}{m}\sqrt{\left(x^2-\frac{1+pp}{n^4+p^2}m^2x^2\right)}$, becomes $\frac{nns}{mmr}\sqrt{\frac{mm+qq}{1+qq}}-x$, whence the semidiameter LM at the point of incidence, which may be called w, and which is analogous to the conjugate diameter AK in the former section, will be

$$\sqrt{\frac{m^4+q^2}{mm+qq}}\cdot\frac{nns}{mmr}\sqrt{\frac{mm+qq}{1+qq}}x=\frac{nns}{mmr}\sqrt{\frac{m^4+q^2}{1+qq}}x.$$

Hence it is obvious that this semidiameter, in any one plane of incidence, will be in a constant proportion to the sines, as Huygens himself demonstrated; so that, supposing x to be constant, and z to vary, the semidiameter w may be considered as an ordinate in the elliptic section passing through the point of incidence M and the diameter AK conjugate to the refracting surface, which is also the path of a ray falling perpendicularly on that surface from without; and the tangent of the angle ELM formed by this semidiameter with the lesser axis of the given section, will be $\frac{mm}{q}$, which determines the intersection of this oblique plane with the refracting surface.

But in order to find the angle made with the refracting surface in a plane perpendicular to it, we must compute LR, the distance of the centre of the refracting section from the point nearest to the centre of the spheroid; and the tangents of the inclinations of the diameters to the axis being p and $\frac{nn}{p}$, that of their mutual inclination will be $\frac{nn+pp}{p(1-nn)}$, since $\tan.(a+b)=\frac{\tan.a+\tan.b}{1-\tan.a\tan.b}$; and the sine of the same angle being expressed by $\frac{\tan.a+\tan.b}{\sec.a\sec.b}$, it becomes here $\frac{nn+pp}{\sqrt{(1+p^2)}\sqrt{(n^4+p^2)}}=\sin.\text{FAK}=\sin.\text{ALR}$, which we may call $\mathfrak{r}$, and the cosine $\frac{1-\tan.a\tan.b}{\sec.a\sec.b}=\frac{p(1-nn)}{\sqrt{(1+p^2)}\sqrt{(n^4+p^2)}}=t$: and the required distance LR will be tz, and the distance of the centre of the spheroid from the refracting surface $\text{AR}=\mathfrak{r}z$. But MS, the perpendicular falling from the point of incidence on the lesser axis of the section formed by the surface, being called u, the tangent of the angle MLS subtended by it at the centre being $\frac{mm}{q}$, and its sine consequently $\frac{mm}{\sqrt{(m^4+q^2)}}$, we have $u=\frac{mmw}{\sqrt{(m^4+q^2)}}=n^2\frac{sx}{r\sqrt{(1+q)}}$; and the distance of this perpendicular from the centre, $\text{LS}=v=\frac{qw}{\sqrt{(m^4+q^2)}}$; or if we call the sine of ordinary refraction $\frac{s}{r}=\varrho$, and the sine of the inclination of the plane of the ray's motion to the lesser axis $\frac{1}{\sqrt{(1+qq)}}=k$, and its cosine $\frac{q}{\sqrt{(1+qq)}}=h$, we have $u=n^2\varrho kx$, and $v=\frac{nn}{mm}\varrho hx$. Hence the cotangent of the angle ERM, formed by the line nearest to the ray in the section with the lesser axis, will be $\frac{v+tz}{u}$ if the value of s be considered as positive, when the ray is inclined on the refracting surface towards the axis of the crystal; for in this case the sign of t being negative, tz or LR will be subtracted from v or LS; and the reverse when s is negative. We have also for the hypotenuse RM, or the distance of the point of incidence from the point nearest to the centre of the spheroid, $\sqrt{(u^2+[v+tz]^2)}$; consequently the tangent of RAM, the angle of incidence or refraction within the crystal, will be $\frac{\sqrt{(u^2+[v+tz]^2)}}{\mathfrak{r}z}$. Now, since it has been shown that $\sqrt{(x^2-\frac{1+pp}{n^4+p^2}m^2z^2)}=\frac{ns}{mr}\sqrt{\frac{mm+qq}{1+qq}}x$, we have $z^2=\frac{n^4+p^2}{mm(1+pp)}\left(1-\frac{nnss}{mmrr}\cdot\frac{mm+qq}{1+qq}\right)x^2$, and the cotangent of the inclination of the plane of refraction ERM, or

$$\frac{v+tz}{u}=\frac{q}{mm}+\frac{tz}{u}, \text{ becomes}$$

$$\frac{q}{mm}+\frac{p(1-nn)}{m(1+pp)}\sqrt{\left(1-\frac{nn}{mm}[m^2k^2+h^2]\varrho^2\right)}\cdot\frac{1}{nn\varrho k};$$

and since $\mathfrak{r}^2z^2=(m^2-n^2\varrho^2[m^2k^2+h^2])x^2$, the tangent of the angle of incidence or refraction within the crystal, which is $=\sqrt{\left(\frac{uu}{\mathfrak{r}\mathfrak{r}zz}+\frac{vv}{\mathfrak{r}\mathfrak{r}zz}+\frac{2t}{\mathfrak{r}}\cdot\frac{v}{\mathfrak{r}z}+\frac{tt}{\mathfrak{r}\mathfrak{r}}\right)}$ will be represented by $\sqrt{\left(\frac{n^4m^4k^2+n^4h^2}{m^4(m^2-n^2\varrho^2[m^2k^2+h^2])}\varrho^2\right.}$

$$+\frac{2p(1-nn)\,nnk\varrho}{\sqrt{(nn+pp)}\,mm\sqrt{(m^2-n^2\varrho^2[m^2k^2+h^2])}}$$

$+\left[\dfrac{p(1-nn)}{nn+pp}\right]^2\Big)$. The value of the perpendicular to the surface, AR or τz, is also of importance, as immediately indicating, by its proportion to the axis x, the velocity of the undulation in the direction of the depth, which is therefore represented by $\sqrt{(m^2-n^2\varrho^2[m^2k^2+h^2])}$.

These expressions become somewhat simpler in many cases of common occurrence. Thus, when the axis is parallel to the surface, $p=0$, $m=n$, and $t=0$, consequently the tangent of refraction is $\dfrac{\varrho}{n}\sqrt{\dfrac{n^4k^2+h^2}{1-(nnkk+hh)\varrho\varrho}}$, and the perpendicular velocity $n\sqrt{(1-[n^2k^2+h^2]\varrho^2)}$. When the axis is perpendicular to the surface, p is infinite, $m=1$, and t is again $=0$; and the tangent of the angle of refraction is $\dfrac{nn\varrho}{\sqrt{(1-nn\varrho\varrho)}}$, the perpendicular velocity being $\sqrt{(1-n^2\varrho^2)}$.

The retardation, produced by the passage of light through such a plate, being equal to the time occupied within the plate, diminished by a time proportional to the product of the tangent of the angle of refraction and the sine of the angle of incidence (see Sect. V.), it will be expressed, in the case of a plate parallel to the axis, by

$$\frac{r}{n\sqrt{(1-[nnkk+hh])\varrho\varrho}}-s\varrho\frac{n^4k^2+h^2}{\sqrt{1-(nnkk+hh)\varrho\varrho}};$$

and when the axis is perpendicular, to the plate, by

$$\frac{r}{\sqrt{(1-nn\varrho\varrho)}}-\frac{snn\varrho}{\sqrt{(1-nn\varrho\varrho)}}=\frac{r(1-nn\varrho\varrho)}{\sqrt{(1-nn\varrho\varrho)}}$$

$=r\sqrt{(1-nn\varrho\varrho)}$. The effect of any small change in the form of the spheroid, on the retardation, may be found from the fluxions of these quantities, supposing n to vary; which, when properly reduced, making $n=1$, will be $-r\dfrac{1-hh\varrho\varrho}{\sqrt{(1-\varrho\varrho)}}\,dn$, and $-\dfrac{r\varrho\varrho}{\sqrt{(1-\varrho\varrho)}}\,dn$ respectively.

The values of r and n, for the principal substances, exhibiting the extraordinary refraction, which have been examined, are these:

Iceland crystal...	$r=$ 1·657	$n=$ 1·1140	$=$ 10 : 9
Arragonite.........	1·693	1·1030	$=$ 11 : 10
Ice..................	1·310	·9989	$=$ 890 : 891
Quartz.............	1·558	·99444	$=$ 179 : 180
Sulphate of lime..	1·525	·99432	$=$ 175 : 176
Sulphate of barita	1·635	·99295	$=$ 142 : 143

In mica, according to Mr Biot, and in arragonite, according to Dr Brewster, there are two axes of crystallization; and the refraction of such substances may probably be represented, by supposing all the circular sections of a spheroid to become ellipses, so that the undulation may assume the shape of an almond.

Sect. XV.—*Of the Colours of doubly refracting Substances.*

In the case of doubly refracting substances, the first difficulty is, not to explain why the colours of double lights are sometimes produced, but why they are not more universally observable; since it might naturally be expected, as a consequence of the general law of interference, that two portions of the same beam, passing through a moderately thin plate of such a substance, in paths differing but little from each other, and coinciding again in direction, should, in all common cases, exhibit colours nearly similar to those of ordinary thin plates. It would, however, be difficult to conjecture whether they ought to resemble the colours seen by transmission or by reflection; and the fact is, that both these series of colours are at once produced by the substances in question; but they are so mixed that, without a particular arrangement, they always neutralise each other; and their formation appears to be also limited to certain peculiar conditions of polarisation, consistent with Mr Arago's observation on the non-interference of two portions of light polarised in transverse directions. Several of the cases, indeed, in which they are exhibited remain still involved in some degree of obscurity; but it is easy to analyse the most important of the phenomena, and to reduce them, with great precision, to the general laws of periodical colours.

Mr Malus has demonstrated, by satisfactory experiments, that a beam of light, admitted into a doubly refracting crystal, is as much divided by partial reflection at the second surface as by transmission at the first; the directions and the relative intensities of the two portions being precisely the same as those of the two portions of a ray similarly polarised, and returning to the second surface from without in an equal angle; so that, after a farther transmission at the first surface, all the portions become again parallel. When the ray is in the direction of the principal section, there is no separation, each of the pencils proceeding undivided, as they would do if they passed through a second crystal parallel to the first; and the separation becomes most complete when the plane of incidence makes an angle of about 45° with the principal section; each of the portions o and e, into which the ray is divided upon its admission, affording then two reflections, oO and oE, eO and eE, of nearly equal intensity. The times occupied by the portions oO, eE, will differ most from each other, while oE and eO will describe their paths in equal times of intermediate length; but of these, eO only will commonly interfere with oO, which has a similar polarisation in the plane of incidence, and oE with eE, both being polarised in a transverse direction; so that we have two series of colours, depending on an equal interval, except so far as they are distinguished by the inversion of one of the portions belonging to the extraordinary reflection, which renders the series of colours exhibited by them similar to that of the colours of common thin plates seen by reflection, while the ordinary reflection exhibits colours analogous to those of thin plates seen by transmission.

Mr Biot's usual mode of exhibiting these colours is to place a thin plate of sulphate of lime, or of any other crystal, on a black substance, to allow it to reflect the white light of the clouds at an angle of incidence of about 55°, and to receive this light on a black glass, at an equal angle of incidence, in a plane transverse to the former, so that the plate may be viewed by reflection in the black glass. In this arrangement, the light reflected from the upper surface of the plate, being polarised in the first plane of reflection is not reflected by the black glass, and consequently is incapable of rendering the colours less easily perceptible by admixture with them; the beams oO and eO, returning by the ordinary reflection, are also similarly polarised, and will be transmitted or absorbed by the glass; but the beams oE and eE, being polarised in a transverse direction, will be partially reflected by it, and will exhibit a very brilliant colour, depending on their mutual interference. If, on the contrary, the black glass be turned round the ray, so that the second plane of incidence may

coincide with the first, the ordinary rays only will be partially reflected by it, and the complementary colour will be exhibited by the union of the portions oO, eO; but this colour will be less distinct, on account of its mixture with the white light reflected by the first surface.

Appearances of a similar nature may also be observed in the transmitted light, each of the refractions exhibiting the colour complementary to that which it affords by reflection, as happens in the ordinary colours of thin plates; and we must seek for the portions of light which afford them in the successive partial reflections at the two surfaces of the plate, as in the case of the ordinary colours; the light simply transmitted by the separate refractions not exhibiting the ordinary effects of interference, for want of a similarity of polarisation. The obliquity of the incident light produces similar effects on both series.

Under some circumstances of the reflection of rays near the perpendicular, Mr Biot observes that the plate assumes the colour which is usually exhibited by a plate of twice the thickness viewed a little more obliquely; and in such cases it is probable that the polarisation of the beams oO and eE has been so modified as to afford a partial interference; and if this is not the true explanation, it will not be difficult to suppose the interval to be doubled in some other manner by a repeated reflection.

The effect of a plate of a double thickness is also produced by two equal and parallel plates, through which the light passes in succession, provided that their axes of crystallization be parallel, and that they be of such a thickness as to exhibit in conjunction a colour more easily observable than those which they afford separately; a condition which is more generally applicable to the case in which the axes are transverse to each other, and one of the thicknesses is to be subtracted from the other; since in this situation the two portions of light must always interchange their refractions, and that which has moved the more slowly in its passage through one of the plates, will move the more rapidly in the other. This result is very accurately confirmed by experiment, and certainly affords a very striking illustration of the truth of the law of interference.

When we wish to examine the effects of the different obliquities of the incident light, it is most convenient to employ a beam previously polarised, which renders the separation of the different portions by a subsequent reflection or refraction more easily practicable; and for these purposes we may either make use of plates of black glass, placed in proper situations, or polarising piles, consisting of a number of oblique thin plates, which produce the effect on the light transmitted through them, with less diminution of its intensity than would take place in a single partial reflection. In some cases, also, the light may be analysed, by causing it to pass through a piece of Iceland crystal; or through a thin plate of agate, which Dr Brewster has found to transmit only such light as is polarised in a particular plane.

The measurements of the thickness of plates of doubly refracting substances agree in general very accurately with the various tints exhibited by them in various situations with respect to the axis, and with various obliquities of the incident light, according to the theory of periodical colours; and the agreement is always sufficiently perfect to convince us of the dependence of the phenomena on the law of interference, even if it should happen to require some unknown modification in particular cases. In the first place, when the incidence is perpendicular, the thickness of the plates is precisely such as would be inferred from the theory, at least as nearly as the theory is founded on observations sufficiently accurate, although this thickness is often many hundred times as great as that of the thin plates with which it is to be compared; thus the greatest disproportion of the ordinary and extraordinary refraction of rock crystal, according to Malus's experiments, is that of 159 to 160; so that the difference of the times occupied by light in passing through this substance is to the interval, in virtue of which a similar plate exhibits the common colours, as 1 to 320, and to the interval in a plate of crown glass as 1 to 318; while the experiments of Mr Biot make the observed proportion that of 1 to 360; the difference being no greater than would arise from an error of less than a thousandth part of the whole, in the determination of one of the refractive densities.

The effect of the obliquity of the incident light, on the colours exhibited by plates of rock crystal, agrees also perfectly with the theory. The difference of the times required for the ordinary and extraordinary refractions, which is always comparatively small, will vary as the fluxion of the retardation when the obliquity varies; and the sine of ordinary refraction being ϱ, the interval will be expressed by $-r\dfrac{1-hh\varrho\varrho}{\sqrt{(1-\varrho\varrho)}}\,dn$ when the axis is parallel to the surface of the plate, and by $-r\dfrac{\varrho\varrho}{\sqrt{(1-\varrho\varrho)}}\,dn$ when it is perpendicular. Taking, for example, an experiment of Mr Biot, on a plate in which the axis was nearly perpendicular, the mean angle of refraction being 21° 38·5′, the tint was a reddish white of the seventh order, answering to the reflection from a plate of glass ·0000496 of an inch thick, in the experiments of Newton, while the colour exhibited, in a perpendicular light, by a plate of the same crystal, in which the axis was parallel to the surface, would have been expressed by the thickness ·000332. In these two cases, the values of the fluxion become $-r\,dn$ and $-·14633r\,dn$; and reducing the interval ·000332 in this proportion, we find ·0000486 for the thickness of a plate of glass which ought to exhibit the tint corresponding to the oblique incidence; the difference from the experiment being only one millionth of an inch, which would scarcely make a sensible alteration in the colour observed. When the thickness of such a plate is more considerable, or when the eccentricity of the extraordinary refraction is greater, the colours differ, with the incidence, in different parts of the plate; and they are generally disposed in rings concentric with the axis. These rings have been particularly described by Dr Brewster, as observed in the topaz; they are always interrupted by a dark cross, occasioned by the want of light, properly polarised to afford them, in the two transverse directions.

Mr Biot has made a great number of experiments on the colours of the plates of sulphate of lime, in the form denominated Muscovy talc. They exhibit a general agreement with the results of the calculation, particularly with respect to the constancy of the tint, in all moderate obliquities, when the inclination of the axis to the plane of incidence is 45°; but in other cases the agreement is somewhat less perfect, and the difference is too great to be attributed altogether to accident. The most probable reason for this irregularity, under circumstances so nearly similar to those which accord with the theory in the case of rock crystal, is the want of a perfect identity of the two refractions, in the direction of the supposed axis; or, in the language employed by Mr Biot with respect to mica, the existence of a double axis of extraordinary refraction: and it is the more credible that such a slight irregularity may have existed in the sulphate of lime without having been observed, as Dr Brewster has detected a similar property in the arragonite, though both Malus and Biot had examined this substance very carefully without being aware of it. The calculation of the extraordinary re-

fraction, in such a case, would afford but little additional difficulty, if its characters were well determined; the form in which the undulations must be supposed to diverge might properly be termed an *amygdaloid*, and the velocities with which the sections formed by the given surface would extend themselves might be deduced from the properties of the ellipsis, nearly in the same manner as they have been determined for the spheroid. The difference of the results of the calculation from the spheroid, and of Mr Biot's experiments, or rather of the empirical formula derived from them, may be seen in the subjoined table; the first part of which, deduced from the theory, is applicable to all substances affording a regular extraordinary refraction, when the axis is either perpendicular or parallel to the surface of the plate. The first column of decimals shows the equivalent variation of thickness where the axis is perpendicular to the plate, being equal to $\frac{\varrho\varrho}{\sqrt{(1-\varrho\varrho)}}$, the product of the sine and tangent of refraction; the second represents the variation for an ordinary thin plate, being proportionable to the cosine $\sqrt{(1-\varrho\varrho)}$; and the subsequent columns are found by adding to the numbers of the second column those of the first, multiplied by k^2, the square of the sine of the inclination of the plane of incidence to the axis, since

$$\frac{1-hh\varrho\varrho}{\sqrt{(1-\varrho\varrho)}}=\sqrt{(1-\varrho\varrho)}+\frac{kk}{\sqrt{(1-\varrho\varrho)}}.$$

Angle of Refraction.	Perpendicular Plate.	Parallel Plate. Inclination of the Plane of Incidence to the principal Section.

There are also some circumstances in the experiments of Mr Biot on plates of rock crystal cut perpendicularly to the axis, which cannot be sufficiently explained on any hypothesis, without some further investigation. These plates seem to transmit the beam of light subjected to the experiment, without materially altering its polarisation, and then to produce different colours, according to the situation of the substance subsequently employed for analysing the light; so that Mr Biot supposes the rays of light to be turned more or less by the crystal, round an axis situated in the direction of their motion; and he has observed some similar effects in oil of turpentine, and in some other fluids. But it is highly probable that all these phenomena will ultimately be referred to some simpler operation of the general law of interference.

Dr Seebeck and Dr Brewster have discovered appearances of colours, like those of doubly refracting substances, in a number of bodies which can scarcely be supposed to possess any crystalline structure. They are particularly conspicuous in large cubes of glass which have been somewhat suddenly cooled, so that their internal structure has been rendered unequal with regard to tension. The outside of a round mass thus suddenly cooled, being too large for the parts within it, must necessarily be held by them in a state of compression with respect to the direction of the circumference, while they are extended in their turn by its resistance; although in the direction of the diameter the whole will generally be in a state of tension; so that the refractive density may naturally be expected to be somewhat different in different directions, which constitutes the essential character of oblique refraction; and when the proportions of the external parts to the internal are modified by the existence of angles, or other deviations from a spherical form, the arrangement of the tensions must be altered accordingly; and there is no doubt that all the apparently capricious variations of the rings and bands of colours which are observed, might, by a careful and minute examination, be reduced to the natural consequences of these inequalities of density, so far at least as the laws of the extraordinary refraction alone are concerned, although the separation of the light into two portions might still remain unexplained. Effects of the same kind are produced by the temporary operation of partial changes of temperature, producing partial compression and extension of the internal structure of the substance; and even a mechanical force, if sufficiently powerful, when applied externally in a single direction, has been shown, by the same observers, to produce a double refraction; although the difference of the densities thus induced is much too minute to be perceived in any other way than by means of these colours, which are in general so much the more easily seen, as the cause which excites them is the feebler.

Dr Brewster has also shown that the total reflection of light within a denser medium, and the brilliant reflection at the surfaces of some of the metals, are capable of exhibiting some of the appearances of colour; as if the light concerned were divided into two portions, the one partially reflected in the first instance, the other beginning to be refracted, and caused to return by the continued operation of the same power. In the case of silver and gold, it has already been observed that there appear to be two kinds of reflection, occasioning opposite polarities; and these may possibly be concerned in the production of this phenomenon. The original interval appears to be extremely minute, but it is capable of being increased by a repetition of similar reflections, as well as by obliquity of incidence. Mr Biot has also found that such surfaces, combined with plates of doubly refracting substances, either increase or diminish the equivalent thickness, according to the direction of the polarisation which they occasion. In these, and in a variety of similar investigations, a rich harvest is opened, to be reaped by the enlightened labours of future observers; and the more difficulty we find in fully explaining the facts, upon the general principles hitherto established, the more reason there is to hope for an extension of the bounds of our knowledge of the optical properties of matter, and of all the laws of nature connected with them, when the examination of these apparent anomalies shall have been still more diligently pursued.

Sect. XVI.—*Of the Nature of Light and Colours.*

Notwithstanding the acknowledged impossibility of fully explaining all the phenomena of light and colours by any imaginable hypothesis respecting their nature, it is yet practicable to illustrate them very essentially, by a comparison with the known effects of certain mechanical causes, which are observed to act in circumstances somewhat analogous; and, as far as a theory will enable us to connect with each other a variety of facts, it is perfectly justifiable to employ it hypothetically, as a temporary expedient for assisting the memory and the judgment, until all doubts are removed respecting its actual foundation in truth and nature. Whether, therefore, light may consist merely in the projection of detached particles with a certain velocity, as some of the most celebrated philosophers of modern times assert; or whether in the undulations of a

certain ethereal medium, as Hooke and Huygens maintained; or whether, as Sir Isaac Newton believed, both of these causes are concerned in the phenomena; without positively admitting or rejecting any opinion as demonstrably true or false, it is our duty to inquire what assistance can be given to our conception and recollection, by the adoption of any comparison which may be pointedly applicable even to some insulated facts only. It has, however, been thought desirable to separate this investigation as much as possible from the relation of the facts, in order to avoid confounding the results of observation with the deductions from mere hypothesis; an error which has been committed by some of the latest and most meritorious authors in this department. It may be objected to some of the preceding sections, that this forbearance has not been exercised with respect to the general law of interference and its modifications; but it would have been impossible to give any correct statement of the facts in question, without determining whether the appearances depend upon one or both of the portions of light supposed to be concerned.

Art. 1. (Sect. I.) The separation of colours is explained, in the hypothesis of emission, by the supposition of an elective attraction, different in intensity for the different rays of the spectrum; but for this difference no ulterior cause is assigned. Any original difference of velocity is contrary to direct experiment; and even the alterations of relative velocity, which must inevitably be occasioned by a variety of astronomical causes, have not been detected by the most accurate observations, instituted for the express purpose of discovering them; so that it has been suggested that there may possibly be a multitude of rays of the same colour, moving with various velocities, and only affecting the sense when they have the velocity appropriate to that colour in the eye. The name of elective attraction is indeed little more than a mode of expressing the fact, without referring it to any simpler mechanical cause; and in chemical elective attractions the substances concerned are under very different circumstances with respect to contact, and with respect to the probable influence of the form and bulk of their integral particles; at the same time it seems impossible to show any absurdity in the supposition of the existence of such an elective attraction with regard to the different kinds of light. On the other hand, if we consider colours as depending on a succession of equal undulations, of different magnitudes as the colours are different, we may discover an analogy, somewhat more approaching to a mechanical explanation, in the motions of waves on the surface of a liquid; the largest waves moving with the greatest rapidity, although the approximate calculation, derived from the most approved theory, leads us to the same expressions for the velocity as are applicable to the transmission of an impulse through an elastic fluid. The fact is, that a larger wave moves more rapidly than a smaller, because the pressure is not precisely limited to a perpendicular direction, as the simplest calculation supposes, but operates also more or less in an oblique direction, principally within a certain angular limit; so that the utmost depth at which any difference of pressure can affect the liquid as a motive force, is that at which this angle may be imagined to comprehend virtually the exact breadth of a wave; and since the velocity depends on the depth of the fluid affected at once by the pressure, the breadth becomes in this manner an element of the determination. Thus also the larger undulations, constituting red light, are found to move more rapidly than those of the violet, which are supposed to be smaller; and there are many ways in which the difference may be supposed to be occasioned, although not depending exactly on the same cause as in the case of the waves on the surface of a liquid. It is well known that sounds of all kinds move with an equal velocity through the air, and all colours arrive through the supposed elastic ether in the same time from the remotest planets; but a refractive medium, however transparent, is not to be considered as perfectly homogeneous; in many instances, two mediums, of different qualities, seem to pervade every part of a crystal, which is completely uniform in its appearance; and it seems to be necessary, in every case, to suppose the particles of material bodies scattered at considerable distances through a medium which passes freely through their interstices; so that we may conceive the undulations of light to be transmitted partly through the particles themselves, and partly through the intervening spaces, the two portions meeting continually after a certain very minute difference in the length of their paths; we may then suppose the portion transmitted through the interstices to be weakened by the irregularity of its passage, which will affect the smaller undulations more than the larger; and when these portions are combined with the portions more slowly transmitted through the particles themselves, these last will bear a greater proportion to the former in the violet than in the red light, and will have more influence on the ultimate velocity, which will therefore be smaller for the violet than for the red. This explanation may perhaps be far from the best that the hypothesis in question might afford; but it will serve as an illustration of a possible mode, in which the phenomenon may be referred to the established laws of mechanics, without the continual introduction of new principles and properties.

Art. 2. (Sect. IV. A.) Most of the ordinary phenomena of optics are capable of a sufficiently satisfactory explanation, on either of the hypotheses respecting the nature of light and colours; but the laws of interference, which have been shown to be so extensively applicable to the diversified appearances of periodical colours, point very directly to the theory of undulation; so directly, indeed, that their establishment has been considered by many persons on the Continent as almost paramount to the establishment of that theory. It might not, however, be absolutely impossible to invent some suppositions respecting the effects of light, which might partially reconcile these laws to the theory of emission. Thus, if we suppose, with Newton, the projected corpuscles of light to excite sensation by means of the vibrations of the fibres of the retina and of the nerves, we may imagine that such vibrations must be most easily produced by a series of particles following each other at equal distances, each colour having its appropriate distance in any given medium; it will then be demonstrable that any second series of similar particles interfering with them, in such a manner as to bisect their intervals, will destroy their effect in exciting a vibratory motion, each succeeding particle meeting the fibre at the instant of its return from the excursion occasioned by the stroke of the preceding, and thus annihilating the motive effect of that stroke. But the illustration ends here; for it seems impossible to adapt it to the greater number of the alternations which occur, during the passage of a ray, through a given space, in a denser medium; since it is an indispensable condition of the projectile theory, that the velocity of light should be increased upon its entrance into a medium of greater refractive density. The Newtonian theory, of fits of easy reflection and easy transmission, is still more limited in its application, since it attributes to one portion of light those effects which have been strictly demonstrated to depend on the presence of two.

In the undulatory theory, the analogy between the laws of interference, and the phenomena of the tides, and the effects of the combination of musical sounds, is direct and

striking. The existence of an undulation of an elastic medium depends on the recurrence of opposite motions, alternately direct and retrograde, at certain equal distances, in the same manner as a series of waves consists in a number of alternate elevations and depressions, and the succession of the tides in a number of periods of high and low water. The spring and neap tides, derived from the combination of the simple solar and lunar tides, afford a magnificent example of the interference of two immense waves with each other; the spring tide being the joint result of the combination, when they coincide in time and place, and the neap when they succeed each other at the distance of half an interval, so as to leave the effect of their difference only sensible. The tides of the port of Batsha, described and explained by Halley and Newton, exhibit a different modification of the same opposition of undulations; the ordinary periods of high and low water being altogether superseded, on account of the different lengths of the two channels by which the tides arrive affording exactly the half interval which causes the disappearance of the alternation. It may also be very easily observed, by merely throwing two equal stones into a piece of stagnant water, that the circles of waves which they occasion obliterate each other, and leave the surface of the water smooth, in certain lines of a hyperbolic form, while, in other neighbouring parts, the surface exhibits the agitation belonging to both series united. The beating of two musical sounds, nearly in unison with each other, appears also to be an effect exactly resembling the succession of spring and neap tides, which may be considered as the beatings of two undulations related to each other in frequency as 29 to 30; and the combination of these sounds is still more identical with that which this theory attributes to light, since the elementary motions of the particles of the luminiferous medium are supposed to be principally confined to the line of direction of the undulation, while the most sensible effects of the waves depend immediately on their ascent and descent, in a direction perpendicular to that of their progressive motion.

Art. 3. (Sect. IV. B.) The diminution of the velocity of light upon its entrance into a denser medium, in the direct proportion of the refractive density, is one of the fundamental principles of the undulatory theory, and is perfectly inadmissible on the supposition of projected corpuscles. But it must be remembered that the demonstration of the actual existence of this proportion is somewhat indirect, being only derived from the necessity of admitting it in the application of the laws of interference to the observed phenomena; and we have no means of obtaining an immediate measure of the velocity of light in different mediums.

Art. 4. (Sect. IV. C.) The loss of the half interval may be explained, in particular cases, without difficulty, although, in other instances, the circumstances are too complicated to allow us to appreciate their effects. In the direct transmission of a ray of light through a plate of a transparent substance, we may compare the denser medium to a series of elastic balls, larger and heavier than another series in contact with them on each side. Now, it is well known that a series of elastic balls transmits any motion from one end to the other, while each ball remains at rest, after having communicated the motion to the next in order, so that the last only flies off, from having none beyond it to impel; and if the balls, instead of being only possessed of repulsive forces, were connected by elastic ligaments of equal powers, a motion in a contrary direction would be transmitted with equal ease; the last ball, being retained by the ligament, instead of flying off, would draw the last but one in the same direction, itself remaining at rest after this negative impulse; and the motion would be communicated backwards in the same manner throughout the series to the first ball; and then, for want of further resistance, this ball would not remain at rest after receiving the negative impulse, but would be drawn forwards by it, so as to strike the second, precisely in the same manner as at the beginning of the experiment; and this second positive impulse would proceed through the whole series like the first. Such is the nature of the longitudinal vibrations of elastic rods, first observed by Chladni; the cohesion of the substance supplying the place of the supposed elastic ligaments; and in the case of an elastic fluid, the pressure of the surrounding parts performs the same office, a negative impulse being always propagated through it with the same facility as a positive one. If, instead of a single series of balls, we now consider the effect of two series, the second consisting of larger balls than the first, the last ball of the smaller series will not remain at rest after striking the first of the larger, but will be reflected, so as to strike the last ball but one in a retrograde direction; and this retrograde impulse will be continued to the first ball, constituting a positive impulse with respect to the new direction in which it is propagated. But if the first series of balls be larger than the second, the last of the larger balls will not be deprived of all its motion by striking the first of the smaller, but will continue to move more slowly in its first direction; and the elastic ligaments will then be called into action, so as to carry back step by step to the first ball this remaining impulse, which will become negative with respect to the new direction of its transmission. And the same must happen in the case of two elastic mediums in contact, supposing them to be of equal elasticity, but of different densities; the direction of the elementary motions either coinciding with that of the general impulse, or being opposite to it in both mediums at once, when the reflection is produced by the arrival of the undulation at the surface of a denser medium, and being reversed when at the surface of a rarer; and it is obvious that such an inversion of any regular undulation is paramount to its retardation or advancement, to the extent of half of the interval which constitutes its whole breadth; every affection of such an undulation being precisely inverted at the distance of half the breadth of a complete alternation: and these effects will not materially differ, whether the impulse be supposed to arrive perpendicularly at the surface, or in an oblique direction.

Art. 5. (Sect. IV. D.; Sect. XIII.) The experiments of Mr Arago, which show that light does not interfere with light polarised in a transverse direction, lead us immediately to the consideration of the general phenomena of polarisation, which cannot be said to have been by any means explained on any hypothesis respecting the nature of light. It is certainly easier to conceive a detached particle, however minute, distinguished by its different sides, and having a particular axis turned in a particular direction, than to imagine how an undulation, resembling the motion of the air, which constitutes sound, can have any different properties with respect to the different planes which diverge from its path. But here the advantage of the projectile theory ends; for every attempt to reduce the phenomena of polarisation to mechanical laws, by the analogy of magnetism, has completely failed of enabling us to calculate the results of the actions of the forces supposed to be concerned, in any correct manner; to say nothing of the extreme complication of the properties which it would be necessary to attribute to the simplest and minutest substances, in order to justify the original hypothesis of a polarity existing in all the particles of light, and a directive attraction, that is, a combination of attraction and repulsion, in every reflecting or refracting sub-

stance. In the undulatory theory we may discover some distant analogies, sufficient to give us a conception of the possibility of reconciling the facts with the theory, and perhaps even of reducing those facts to some general laws derived from it; although it will be necessary, in this intricate part of the inquiry, to proceed analytically rather than synthetically, and to rest satisfied for the present, without bringing the analysis to a termination by any means explanatory of all the phenomena. Some of the supporters of this theory may perhaps be of opinion that its deficiencies are too strongly displayed by this attempt; but it is for them to find a more complete solution of the difficulties, if any such can be discovered.

In the case of a wave moving on the surface of a liquid, considering the motion of the particles at some little distance below the surface as concerned in the propagation of an undulation in a horizontal direction, we may observe that there is actually a lateral motion, throughout the liquid, in a plane of which the direction is determined by that of gravitation; but this happens because the liquid is more at liberty to extend itself on this side than on any other, the force of gravitation tending to bring it back with a pressure of which the operation is analogous to that of elasticity; and we cannot find a parallel for this force in the motions of an elastic medium. It is indeed very easy to deduce a motion, transverse to the general direction, from the combination of two undulations proceeding from two neighbouring points, and interfering with each other, when the difference of their paths amounts to half an interval; for the result of this combination will be a regular though a very minute vibration in a transverse direction, which will continue to take place throughout the line of the propagation of the joint motions, although certainly not with any force that would naturally be supposed capable of producing any perceptible effects. There must even be a difference in the motions of the particles in every simply diverging undulation, in different parts of the spherical surface to which they extend; for, supposing it to originate from a vibration in a given plane, the velocity of the motion constituting the undulation will be greatest in the direction of that plane, and will disappear in a direction perpendicular to it, or rather will there become transverse to the direction of the diverging radii; and in all other parts there must be a very minute tendency to a transverse motion, on account of the difference of the velocities of the collateral direct motions, and of the compressions and dilatations which they occasion. When, also, a limited undulation is admitted into a quiescent medium, it loses some of its force by diffraction on each side, where it is unsupported by the progress of the collateral parts; and if an undulation were admitted by a number of minute parallel linear apertures or slits, or reflected from an infinite number of small wires, parallel to each other, it would still retain the impression of the incipient tendency to diffraction in all its parts, producing a modification of the motion, in a direction transverse to that of the slits or wires. It is true that all these motions and modifications of motion would be minute beyond the power of imagination, even when compared with other motions, themselves extending to a space far too minute to be immediately perceived by the senses: and this consideration may perhaps lessen the probability of the theory as a physical explanation of the facts; but it would not destroy its utility as a mathematical representation of them, provided that such a representation could be rendered general, and reducible to calculation; and, even in a physical sense, if the alternative were unavoidable, it is easier to imagine the powers of perceiving minute changes to be all but infinite, than to admit the portentous complication of machinery, which must be heaped up, in order to afford a solution of the difficulties which beset the application of the doctrine of simple projection to all the phenomena of polarisation and of colours. It is not however possible at present to complete such a mathematical theory, even on imaginary grounds; although a few further analogies between polarisation and transverse motion force themselves on our observation.

In the theory of emission, the resemblance of the phenomena of polarisation to the selection of a certain number of particles, having their axes turned in a particular direction, supposing these axes, like those of the celestial bodies, to remain always parallel, will carry us to a certain extent, in estimating the quantity of light contained in each of the two pencils into which a beam is divided and subdivided; but it would soon appear that, after a few modifications, this parallelism could no longer be supposed to be preserved: we should also find it impossible to assign the nature and extent of any forces which might be capable of changing the former directions of the axes, and fixing them permanently in new ones. The distinction of a fixed, a movable, and a partial polarisation, which has been imagined by Mr Biot, must vanish altogether, upon considering that all the effects which he attributes to the partial polarisation are observable in experiments like those of Mr Knox, in which there is confessedly no polarisation at all.

If we assume as a mathematical postulate, in the undulatory theory, without attempting to demonstrate its physical foundation, that a transverse motion may be propagated in a direct line, we may derive from this assumption a tolerable illustration of the subdivision of polarised light by reflection in an oblique plane. Supposing polarisation to depend on a transverse motion in the given plane, when a ray completely polarised is subjected to simple reflection in a different plane, which is destitute of any polarising action, and may therefore be called a neutral reflection, the polar motion may be conceived to be reflected, as any other motion would be reflected, at a perfectly smooth surface, the new plane of the motion being always the image of the former plane; and the effect of refraction will be nearly of a similar nature. But when the surface exhibits a new polarising influence, and the beams of light are divided by it into two portions, the intensity of each may be calculated, by supposing the polar motion to be resolved instead of being reflected, the simple velocities of the two portions being as the cosines of the angles formed by the new planes of motion with the old, and the energies, which are the true measure of the intensity, as the squares of the sines. We are thus insensibly led to confound the intensity of the supposed polar motion with that of the reflected light itself; since it was observed by Malus, that the relative intensity of the two portions into which light is divided under such circumstances, is indicated by the proportion of the squares of the cosine and sine of the inclination of the planes of polarisation. The imaginary transverse motion might also necessarily be alternate, partly from the nature of a continuous medium, and partly from the observed fact, that there is no distinction between the polarisations, produced by causes precisely opposed to each other, in the same plane.

Why light should or should not be reflected at certain surfaces, when it has been previously polarised, cannot, even with the greatest latitude of hypothesis, be very satisfactorily explained; but it is remarkable that the transmission is never wholly destroyed, or even weakened in any considerable proportion. We might, indeed, assign a reason for the occurrence of a partial reflection or a total transmission in the constitution of the surface concerned, since every abrupt change of density must necessarily produce a partial reflection, while a gradual transition by insensible steps must transmit each impulse with undimi-

nished energy, and without any reflection of finite intensity, as in the well-known case of a collision supposed to be performed with the interposition of an infinite number of balls of all possible intermediate magnitudes. If, therefore, we could find any modification of light, which could cause it to be transmitted from one medium to another in a more or less abrupt manner, we should thus be able to discover a cause of a variation of the intensity of the partial reflection; and this seems to be the nearest approach that we can at present make to an explanation of the phenomenon, according to the undulatory theory.

Art. 6. (Sect. V.) The equal intensity of the colours of thin plates, seen by reflection and by transmission, is a fact which would not have been expected from the immediate application of the law of interference, and which seems, therefore, at first sight to militate against its general adoption. But this is only one of the many modifications of the law, which are the immediate consequences of its connection with the undulatory theory; and it may be demonstrated, from the analogy of a series of elastic bodies, that no material difference in the intensity of the two kinds of colours ought to be expected in such circumstances. The intensity of a ray of light must always be considered as proportional to the energy or impetus of the elementary motions of the particles concerned, which varies as the square of the velocity, and not simply as the velocity itself; for if the velocity were made the measure of intensity, there would be an actual gain of joint intensity whenever a ray is divided by partial reflection; since it follows from the laws of the motion of the centre of inertia, that when a smaller body strikes a larger, not the sum, but the difference of the separate momenta, will remain unchanged by the collision, while the sum of the energies remains constant in all circumstances; the square of a negative quantity being equal to that of the same quantity taken positively. Thus, supposing an elastic ball, 1, to strike another, of which the mass is r, with the velocity 1, the velocity of the transmitted impulse will be $\frac{2}{r+1}$, and that of the reflected, $\frac{2}{r+1}-1=-\frac{r-1}{r+1}$, the sum of the momenta in the opposite directions being $\frac{3r-1}{r+1}$, instead of 1, the original momentum; but the energies expressed by the products of the masses into the squares of the velocities will be $\frac{4r}{(r+1)^2}$, and $\left(\frac{r-1}{r+1}\right)^2$ respectively; and the sum of these is $\left(\frac{r+1}{r+1}\right)=1$. Now, when an impulse arrives at the last of a series of larger particles, and is reflected in an inverted form, if we substitute $\frac{1}{r}$ for r, the energies will be in the proportion of $\frac{4}{r}$, and $\left(\frac{1}{r}-1\right)^2$, or of $4r$ and $(1-r)^2$, which is the same as the former; so that, according to this analogy, the subdivision of the light at the second surface of a plate must be in the same proportion as at the first. We may call this proportion that of m^2 to n^2, m^2+n^2 being equal to 1; we have then n^2 for the energy of the first partial reflection, m^2n^2 for the second, and m^2n^4 for the third; for the first transmission, into the substance, m^2; for the second, out of it, m^4; for the third, after an intermediate reflection, m^4n^2; and for the fourth, after two reflections, m^4n^4; and the elementary velocities in either medium, compared among themselves, will be as the square roots of the respective energies. But it may be proved that, in all collisions of two moving bodies, each of the motions produces its effect on the velocities after impulse, independently of the other; so that the changes introduced, in consequence of the motion of one of the bodies concerned, are the same as it would have occasioned if the other had been at rest; and, consequently, if two undulations interfere in any manner, the joint velocities of the particles must always be expressed by the addition or subtraction of the separate velocities belonging to the respective undulations. When, therefore, the beam first partially reflected, of which the elementary velocity is expressed by n, interferes with the beam transmitted back, after reflection at the second surface, with the velocity m^2n, the joint velocity, in the case of the perfect agreement of the motions, will be $n+m^2n$, and in case of their disagreement, $n-m^2n$; the energies being $(n+m^2n)^2$ and $(n-m^2n)^2$; the difference, which is the true measure of the effect of the interference, being $4m^2n^2$, that is, four times the product of the respective velocities. But when the light simply transmitted at the second surface, with the velocity m^2, interferes with the light transmitted after two reflections, with the velocity m^2n^2, the quadruple product becomes $4m^4n^2$, only differing from the former in the ratio of m^2 to 1, which is that of the intensity of the light transmitted by the single surface to the intensity of the incident light, the difference being much too slight to be directly perceived by the eye; so that this result may be considered as agreeing perfectly with Mr Arago's observation.

We may also obtain, from the analogy with the effects of collision, an illustration of the intensity of the partial reflection in different circumstances; although it is not easy to say what ought to be the precise value of r in the comparison. If we imagined the two mediums to differ only in density, while their elasticity remained equal, which is the simplest supposition, the density must be conceived to vary as the square of the velocity appropriate to the medium; but the value of r thus determined makes the partial reflection in general much too intense, and it becomes necessary to suppose it weakened by the intervention of a stratum of intermediate density, such as there is every reason to attribute to the surfaces of material substances in general, from the considerations stated in the article COHESION. However this may be, we shall in general approach sufficiently near to a representation of the phenomenon, by taking the mass r in the simple proportion of the refractive density: thus, in the case of water, making $r=\frac{4}{3}$, we have for the energy of the first partial reflection $\left(\frac{r-1}{r+1}\right)^2 = \frac{1}{49} = \cdot 0204$, while the result of Bouguer's experiments is $\cdot 018$; and the agreement is as accurate as could have been expected, even if the whole calculation had not been an imaginary structure. In the case of glass, the difference is somewhat greater; and it is natural to expect a greater loss of light from a want of perfect polish in the surface; for, taking $r=\frac{3}{2}$, we have $n^2=\cdot 040$, and Bouguer found the reflection only $\cdot 025$. The surface of mercury reflected nearly $\cdot 60$; whence r should be about 8. Whether the index of the refractive density can be so great as this, we have no precise mode of determining; but there seems to be something in the nature of metallic reflection not wholly dependent on the density. Thus it may be observed, that potassium has a very brilliant appearance, though its specific gravity is very low; at the same time, its great combustibility might give it a much higher rank among refractive substances than could otherwise have been expected from its actual density.

Art. 7. (Sect. XIII.) Although the ingenuity of man

has not yet been able to devise any thing like a satisfactory reason for the reflection of a polarised ray in one case, and its transmission in another, yet several attempts have been made, with various success, to reconcile the different hypotheses of light with the other phenomena of oblique refraction. The illustrious M. Laplace has undertaken to reduce the laws of this refraction, according to the projectile system, from the general doctrines of motion; and he has sufficiently demonstrated that the path followed by the light is always such as to agree with the principle of the least action, supposing the law of the velocities previously established; or, in other words, that the sum of the products of the spaces described, into the respective velocities, is always the least possible. To this demonstration it has been objected, that notwithstanding the complication of its steps, it is in fact nothing more than the simple translation of the fundamental law of Huygens into another language; for it is assumed in this theory, upon obvious and intelligible grounds, that the path of light must always be such that the time may be equal with respect to two neighbouring collateral parts of the undulation, which is the well-known condition of a minimum of the whole time employed; and the time being always expressed by the space divided by the velocity, if we suppose the proportions of the velocities to be inverted, as in the two theories respecting light, the expression of the time in the one will be identical with that of the action in the other; consequently the conditions of the propagation of light, in the Huygenian doctrine, must always imply the observation of the law of least action in the opposite hypothesis; and this general proposition M Laplace has taken great pains to prove with respect to a particular instance, in which the Huygenian calculation had been found, notwithstanding Newton's doubts, to agree perfectly with the phenomena. It has also been observed, that the law of the least action is wholly inadmissible as a fundamental principle of motion; that it is completely unphilosophical to multiply unnecessarily the number of postulates or elementary laws; and that although in many cases the principle may be capable of being established as a derivative proposition, yet, in order to demonstrate it, we must assume that the velocity must be the same in all directions, between the same parallel or concentric surfaces, or at any rate must limit our reasoning by conditions incompatible with the nature of the actions, to be considered as the foundation of the laws of extraordinary refraction.

In this single point, the undulatory theory has every possible advantage over its rival. For the difference of the velocities in different directions, no force has been assigned as a cause, in the projectile system, at all more general than the individual directions of the rays with respect to the axis. But upon the hypothesis of undulations, it has been demonstrated, without any gratuitous supposition, that every lamellar or fibrous substance must transmit every diverging impulse in the form of a spheroidal surface, supposing only the elasticity to act more powerfully in one direction than another, as it naturally must do in such circumstances. (*Quarterly Review*, No. iv.) And when we consider the experiments of Dr Brewster and Dr Seebeck, which show that any compression or extension whatever, acting in a given direction on any transparent solid, is capable of occasioning those appearances of colour which prove the transmission of light by an ordinary and extraordinary refraction, we cannot help imagining that the cause of the elliptic refraction must be of a nature more simple than is consistent with the existence of a multiplicity of attractions, and repulsions, and polarising powers, acting in all manner of directions, with every possible variation of intensity, independently of any assignable variation of the circumstances of the light affected.

There is however another mode of considering the mechanism of elliptic refraction, which is somewhat less simple and elementary, but which affords us a further analogy to the phenomena of polarisation by reflection and transmission. If we suppose a doubling crystal to consist of a large number of very thin plates, united by a medium differing but little from them in refractive density, this pile will completely polarise the transmitted light, as Malus and Dr Brewster have shown, in a plane perpendicular to that of the incidence, even when the inclination of the surfaces is widely different from that which produces the most complete polarisation at once; and at the same time a part of the light, partially reflected by each plate, will be again reflected by the neighbouring surfaces into its original direction; nor will it be difficult to imagine that the quantity of light thus twice reflected may, from some unknown cause, be rendered ultimately equal to that of the light simply transmitted, which, according to the laws of polarisation, will never exceed half of the original beam. Now the lengths of the paths of these two portions will not only be different, but the difference will vary according to the direction; for while the light simply transmitted proceeds to describe its path, with the uniform velocity belonging to the mean of the two mediums, combined always in a constant proportion, the light twice reflected by each plate will be retarded most of all in the direction perpendicular to the plates, as in the case of the colours of common thin plates; and in oblique directions, the number of plates which it has to pass through in a given space being as the cosine of the angle of incidence, and the retardation in each plate being also as the same cosine, neglecting the difference between the angles of incidence and refraction, which is supposed to be inconsiderable, the whole retardation will be as the square of the cosine of the inclination to the axis, which is the well-known proportion of the difference of the diameters of a circle, and of an ellipsis approaching near in it. We thus obtain a general idea of the combination of two effects which do not appear to be related in any other point of view, a regular oblique refraction and a distinct polarisation; further than this, the comparison is by no means completely satisfactory; and the great difficulty of all, which is to assign a sufficient reason for the reflection or non-reflection of a polarised ray, will probably long remain, to mortify the vanity of an ambitious philosophy, completely unresolved by any theory. (T. Y.)

CHROMIUM, one of the metals. See CHEMISTRY.

CHRONIC, a term applied to diseases of long continuance, in contradistinction to those that speedily terminate, which are called acute.

CHRONICLE, an historical register of events in the order of time. Chronicle is nearly synonymous with annals.

CHRONICLES, the name given to two books of the Old Testament, standing thirteenth and fourteenth in our English collection, but variously placed in the lists of the Masorets, Talmudists, and Fathers. Eichhorn (*Einleitung* § 7) and De Wette (*Kurzgefasstes exegetisches Handbuch zum Neuen Testament*, Bd. i. 247), with many others in recent times, contend, from the mention of Zacharias, son of Barachias, in Matt. xxiii. 35. (whom they identify with Ze-

chariah, son of Jehoiada, in 2 Chron. xxiv. 19–22), that they must have stood last in the order of the canonical Scriptures, because thus alone could the two events there mentioned be pointed out as conspicuous landmarks, inclusive of all Old Testament martyrology. The difficulties, however, which beset the interpretation of both passages—the definitely marked chronology of the martyrdom in the Old Testament, with the obvious latitude required by the commination in the New—render this objection of comparatively little force. In Hebrew the Chronicles have the title of *Words of the Days* or *Journals*, and form, as their internal character sufficiently demonstrates, one book; but in the Alexandrine version they form two books under the name *Paraleipomena* or *things omitted*, a title which recognises them as standing in a merely supplementary relation to the previous histories. The name of *Chronicles* does not remount beyond the time of Jerome, and is obviously less correct than the Alexandrine designation.

The Book of Chronicles (for we shall speak of them as one) opens with a variety of lists, principally genealogical; but these are neither complete nor coextensive with the Jewish tribes, Dan and Zebulon being omitted, while peculiar prominence is given to Benjamin. After these it gives the history of David, entirely harmonizing with the earlier account of Samuel, but regarding it from a more purely theocratic point of view. From the establishment of the monarchy under David it narrates the increasing glory of the Jewish kingdom under Solomon, and traces its decline in that last and most vital of the two branches into which it was at his death divided, viz. the kingdom of Judah. This latter part of the history is continued after the fall of Israel, and with particular reference to the vicissitudes in the history of Jewish worship. The narrative is brought down till after the exile; and one of the genealogies (1 Chron. iii. 19–24, which, however, Eichhorn, Dahler, Jahn, and Keil, regard as a later addition) seems to be continued till the time of Alexander.

The comparatively late origin of the book of Chronicles is as strongly marked in the enfeebled Aramaic colouring which everywhere overspreads the diction as by the chronological notes which are to be found in the narrative. The same inference may be allowed from the special jealousy in behalf of sacerdotal institutions which the writer manifests, and which is evidently in keeping with the whole tone of the later prophetic denunciations. In regard to the authorship of the book, the invariable Jewish tradition is in favour of Ezra, and this is generally regarded as sufficiently borne out by the peculiarities of its style and idiom, and as directly shown in the obvious connection subsisting between the close of the narrative in the Chronicles and the opening of the book which bears his name. Several recent critics, however, partly on historical and partly on literary considerations, attribute it to some unknown author, who is in all probability to be found in the priesthood. The sources from which the materials have been derived are incidentally given in the record itself, and comprehend a great variety of books which have not been admitted into the canon. Some have denied that the author drew any information from the previous historical books; but this has been generally conceded, and it seems difficult otherwise to account for the marked similarity which obtains between them.

The most important subject of debate in regard to the book of the Chronicles, is that which affects the integrity of the text and the accuracy of the history. One or other of these is surrendered by either of two parties; those who uphold the historical accuracy of the record deny the immaculate integrity of the text; while those who uphold the integrity of the text, as a necessary consequence, impeach the historical accuracy of the record. A third party who, in a narrative so unmistakably one in style and spirit, seek by a process of delicate criticism to eliminate the spurious additions of later hands, have by the inconsistency of their results signalized the worthlessness and failure of the scheme. As these are questions of purely historical criticism, in which ethical considerations find no place, it is idle to appeal to the consentient voice of the synagogue and the church as furnishing any ground of decision in the case; and thus it is unnecessary here to give any details in regard to the exegetic history of the book. The textual corruption postulated on the one hand, and the historical inaccuracy postulated on the other, have varied greatly in amount at different epochs, and are always in striking disproportion. The former is gradually subsiding to a minimum of some six or seven instances—most of them arising immediately from the delicacies of Hebrew orthography and numeration—while under the pressure of the destructive criticism which has long prevailed abroad, the former has reached a maximum so largely aspersing the general character of the book that it were an easier task to estimate the small residuum of accuracy than the mass of error which it contains. To arrive at this latter result the fragmentary and disjointed character of the book is wholly overlooked, and every chasm is unhesitatingly reckoned an inaccuracy, every variation in statement from the earlier books a deviation from truth, every retrenchment an apologetic omission, and every addition an edifying gloss. (See De Wette's *Introduction to the Canonical Books of the Old Testament*, who on this side of the question may be said to have exhausted the subject). But this is not all; critics of this class have gone a step further, and regard the inaccuracy as systematic and designed. Applying the *cui bono* principle (who profits by the fraud?) they find the key to all the corrections, retrenchments, and additions in the growing influence and arrogance of the priesthood who sought to consolidate and aggrandize the power of their order by thus clumsily exaggerating their influence on the previous history of the nation. For this purpose they, or the writer who represents them, have endeavoured to throw a sacerdotal colouring over every transaction, concealing everything that would lower the orthodox or exalt the idolatrous kings in popular estimation, overstating the respective numbers of the tribes, and values of the offerings to the temple. Against this hypothesis it is enough to plead—independent of the monstrosity of the supposition which it necessarily involves, that the whole Jewish Levitical system was the work of time and chance and personal intrigue—the entire absence of that superficial accuracy which invariably marks all such disingenuous productions, and the ease with which the seeming contradictions, with the exception of a very few otherwise readily accounted for, can be reconciled. (See this ably shown in Dr Samuel Davidson's *Sacred Hermeneutics developed and applied.*) Besides this, the scope and style of the book admits of a higher and truer explanation. Psychologically it stands in immediate connection with the mission of the ecclesiastical reformer who was its author, and historically with the reforms which he was instrumental in executing; while as the last of the genealogical records it served at once to fix the line and prepare the way of the last and greatest priesthood. (R. W—N.)

CHRONOLOGY.

CHRONOLOGY, from χρονος, *time*, and λογος, *word* or *description*, is the science which treats of time. Its object is to arrange and exhibit the various events which have occurred in the history of the world in the order of their succession, and to ascertain the intervals of time between them.

The preservation of any record, however rude, of the lapse of time, implies some knowledge of the celestial motions, by which alone time can be accurately measured, and some advancement in the arts of civilized life, which could only be attained by the accumulated experience of many generations. Before the invention of letters, the memory of past transactions could not be preserved beyond a few years with any tolerable degree of accuracy. Events which greatly affected the physical condition of the human race, or were of a nature to make a deep impression on the minds of the rude inhabitants of the earth, might be vaguely transmitted through several ages by traditional narrative; but intervals of time, expressed by abstract numbers, and these too constantly varying, would soon escape from the memory. The invention of the art of writing afforded the means of substituting precise and permanent records for vague and evanescent tradition; but in the infancy of the world mankind had neither learned to estimate accurately the duration of time, nor to refer passing events to a fixed and determined epoch. Writing was practised many centuries before historians began to assign dates to the events they narrated.

For these reasons the history of the early ages of the world is involved in impenetrable obscurity, and chronology, comparatively speaking, is only of recent date. After political relations began to be established, the necessity of preserving a register of passing seasons and years would soon be felt, and the practice of recording important transactions must have grown up as a necessary consequence of social life. But of these early records, how small a portion has escaped the ravages of time and barbarism? The annals of the early Greeks and of the Etruscans are irretrievably lost. Of the chronicles which Manetho, high priest of Sebenne, professed to have reduced from the archives of the Egyptian temples; of the histories of Sanconiathon the Phœnician, of Berosus, Hecatæus, and others, only a few mutilated fragments have been transmitted to our times through the suspected relation of Josephus, Julius Africanus, Eusebius, Syncellus, and other chronologers. The Gauls destroyed the records of ancient Rome. The Romans, in their turn, extirpated the Druids of Gaul and Britain, and obliterated the last vestiges of their ancient traditions. An Arab chief burned the library of Alexandria, a Chinese emperor the histories of his own country, and a Spanish soldier the paintings and hieroglyphics of the palace of Montezuma.

In order to preserve an exact record of the succession of events, some conventional *epoch*, or fixed point of time, must be taken as the origin of the reckoning, and some standard period assumed with which the successive intervals may be compared. It is a trite remark, that the simplest ideas are generally the latest in representing themselves to the mind. Nothing seems more obvious than to measure the longer intervals of time by the tropical revolutions of the sun, and to number the years in regular succession. But this simple method was not adopted by historians in the earliest ages. In the Scripture history the lapse of time is frequently estimated by generations, or reigns of kings, and not by exact numbers of years. The historians of early Greece proceeded in a similar manner. Hellanicus regulated his narrative by the succession of the priestesses of Juno in the temple of Argos. Others reckoned by the ephori and kings of Sparta, or the archons of Athens. Ephorus, the disciple of Isocrates, who composed a chronological history of Greece, reckoned by generations. Eratosthenes and Apollodorus, who flourished about a hundred years after the death of Alexander the Great, first attempted to introduce precision into historical records, by substituting numbers of years for generations, reigns, or successions. (See Newton's *Chronology*, Introduction). Now, when time is measured by any of the above methods, it is obvious that we can only approximate to the intervals between successive events, from our knowledge of the average duration of human life, and of kings' reigns, in the present state of the world. Chronologers usually reckon three generations equivalent to a hundred years, and Sir Isaac Newton allows eighteen or twenty years to a reign or succession. In a great number of years this estimate is probably near the truth, but it affords very uncertain information with respect to short periods, and none whatever with regard to the duration of an individual reign. It is to those loose methods of marking the lapse of time that we must ascribe the great discrepancy that exists among the chronological accounts of the early ages of Greece and Rome.

Another great cause of uncertainty and confusion in chronology has arisen from the diversity of epochs assumed by historians, and the practice, which has been unhappily too prevalent, of shifting the origin of their eras from one epoch to another. Having little intercourse with each other, the different groups or communities into which mankind were divided in early times, instead of agreeing on a common epoch, began each to date the years from some event, important perhaps in reference to its individual history, but of which other tribes were probably entirely ignorant, or which at least they regarded with indifference. Hence in ancient history we have the Olympiad of Corœbus, the foundation of Rome, the era of Nabonassar &c.; and in more recent times the Christian era, the Hegira, the era of Yezdegird, &c. Some centuries after the introduction of Christianity, the various sects of Christians began to found their eras on events connected with the appearance of Christ, but without any regard to uniformity. Some reckoned from the epoch of his conception, or the annunciation; others from his birth, others again from his passion, others from his ascension; and hence there is very frequently the greatest difficulty in reconciling the dates given by the historians and annalists of the middle ages.

In reckoning years from any fixed epoch in constant succession, the numbers denoting the years necessarily undergo a constant and unlimited augmentation. But rude nations, and illiterate people in general, seldom attach any definite idea to large numbers. Hence it has been a practice, very extensively followed, to employ cycles or periods, containing a moderate number of years, and to distinguish and reckon the years by their number in the cycle. The Chinese, and some other nations of Asia, reckon not only the years, but also the months and days, by cycles of sixty. The Saros of the Chaldeans, the Olympiad of the Greeks, and the Roman Indiction, are instances of this mode of reckoning time. Several cycles were formerly known in Europe; but most of them were invented for the purpose of adjusting the solar and lunar divisions of time, and were

rather employed in the regulation of the calendar than as chronological eras. They are frequently, however, of very great use in fixing dates that have been otherwise imperfectly expressed, and consequently form important elements of chronology.

In the article Calendar, we have already treated of that part of Chronology which relates to the measurement of time, and explained with sufficient detail the principal methods that have been employed, or are still in use, for adjusting the lunar months to the solar year, as well as the intercalations necessary for regulating the civil year according to the celestial motions. In the present article it is our purpose to give an account of the different *Eras* and *Periods* that have been employed by historians, and by the different nations of the world, in recording the succession of time and events; to fix the epochs at which the eras respectively commenced; to ascertain the form and the initial day of the year made use of; and to establish their correspondence with the years of the Christian era. These elements will enable us to convert, by a simple arithmetical operation, any historical date, of which the chronological characters are given according to any era whatever, into the corresponding date in the common era of the Incarnation.

Julian Period.

Although the Julian period is not, properly speaking, a chronological era, yet, on account of its affording considerable facilities in the comparison of different eras with one another, and in marking without ambiguity the years before Christ, it is very generally employed by chronologers. It consists of 7980 Julian years. The number 7980 is formed by the continued multiplication of the three numbers 28, 19, and 15, that is, of the cycles of the sun, of the moon, and of the Indiction: hence, when the number of any year in the Julian period is divided by one of these three numbers, the remainder of the division will indicate the number of that year in the corresponding cycle. The first year of the Christian era had ten for its number in the cycle of the sun, two in the cycle of the moon, and four in the Indiction; but 4714 is the only number less than 7980 which, on being divided by 28, 19, and 15, gives the respective remainders 10, 2, and 4 (See Calendar). Hence the first year of the Christian era corresponded with the year 4714 of the Julian period. In order, therefore, to find the year of our era corresponding to any other year of the period, or the contrary, we have the following rule:

1. When the given year is anterior to the commencement of the Christian era, subtract the number of the year in the Julian period from 4714, and the remainder is the year before Christ: or subtract the year before Christ from 4714, and the remainder is the corresponding year in the Julian period.

2. When the given year is after Christ, subtract 4713 from the year of the period, and the remainder is the year of the Christian era; or add 4713 to the year of Christ, and the sum is the corresponding year of the Julian period.

Olympiads.

The Olympic games, so famous in Grecian history, were celebrated once every four years, between the new and full moon first following the summer solstice, on the banks of the river Alpheus, near the city of Pisa, in the Peloponnesus, and lasted five days. They are said to have been originally instituted by Hercules, at the funeral ceremonies of Pelops, 1354 years before the Christian era; but they seem to have been forgotten, or at least to have been discontinued, during several centuries. They were afterwards re-established by Iphitus, king of a canton of Elis, in concert with Lycurgus and Cleosthenes of Pisa, 844 years before Christ, and 470 years from the time of their original institution; but it was not till upwards of a hundred years after this time that they began to be used as a chronological epoch. It was then that the practice was adopted of designating the Olympiad, or period of four years, by the name of the victor in the contests of the stadium, and of inscribing his name in the gymnasium of Olympia. The first who received this honour was Corœbus. The games in which Corœbus was victor, and which form the principal epoch of Grecian history, were celebrated about the time of the summer solstice, 776 years before the common era of the Incarnation, in the 3938th of the Julian period, and twenty-three years, according to the account of Varro, before the foundation of Rome.

Form of the Olympic Year.—Before the introduction of the Metonic cycle, the ordinary Grecian year consisted of twelve lunar months, containing twenty-nine and thirty days alternately; and in order to reconcile this with the course of the sun, a thirteenth month was added, at first every second year, and subsequently three times in eight years. The additional or intercalary month contained thirty days, so that the *Octaeteris*, or period of eight years, consisted of ninety-nine months, containing in all 2922 days, which is exactly equal to eight Julian years. The years which contained the intercalary month were called *embolismic*, and formed the third, fifth, and eighth of the period. Hence the Olympiads contained forty-nine and fifty months alternately, the first four years of the Octaeteris containing one intercalary year, and the second two; and hence, also, the Olympic games were celebrated alternately on common and embolismic years. It has been shown in the article Calendar, that the Octaeteris fell short of the actual length of ninety-nine lunations by a day and a half nearly; at the end of two periods, therefore, the moon's age was three days less than it had been at the commencement, and in order to restore the coincidence between the civil month and the lunation, three days were added to the last year of each second Olympiad. But this correction introduced an error in respect of the sun, and caused the solar year to commence three days too late. This error was allowed to accumulate till the end of the fortieth Olympiad, when a full month of thirty days was omitted, by which means the solar and lunar years were adjusted, and the forty-first Olympiad commenced with the same day of the moon, and the same season of the year, as the first had done 160 years before. According to this arrangement the common years contained 354 days, and the embolismic 384; excepting however the concluding year of each second Octaeteris, which contained 387 days, and the last year of each fortieth Olympiad, which had 357 days.

In the fourth year of the eighty-sixth Olympiad, Meton published his celebrated cycle of nineteen years, which, after receiving a slight correction from Calippus, continued to be followed ever afterwards, so long as the practice of dating by Olympiads continued in use. Before the introduction of the Metonic cycle, the Olympic year began sometimes with the full moon which followed, sometimes with that which preceded, the summer solstice, on account that the year sometimes contained 384 days instead of 354; but subsequently to its adoption, the year always commenced with the eleventh day of the moon which followed the solstice. In order to avoid troublesome computations, which it would be necessary to recommence for every year, and of which the results differ from one another only by a few days, chronologers in general regard the first of July as the commencement of the Olympic year. Some authors, however, among whom are Eusebius, Jerome, and the historian Socrates, place its commencement at the first of September; but they seem to have confounded the Olym-

pic year with the civil year of the Greeks, or the era of the Seleucidæ.

It is material to observe, that as the Olympic years and periods begin with the first of July, the first six months of a year of our era correspond to one Olympic year, and the last six months to another. Thus, when it is said that the first year of the Incarnation corresponds to the first of the 195th Olympiad, we are to understand that it is only with respect to the last six months of that year that the correspondence takes place. The first six months belonged to the fourth year of the 194th Olympiad. In referring dates expressed by Olympiads to our era, or the contrary, we must therefore distinguish two cases.

1st, When the event in question happened between the first of January and the first of the following July, the sum of the Olympic year and of the year before Christ is always equal to 776. The year of the era, therefore, will be found by subtracting the number of the Olympic year from 776. For example, Varro refers the foundation of Rome to the 21st of April of the third year of the sixth Olympiad, and it is required to find the year before our era. Since five Olympic periods have elapsed, the third year of the sixth Olympiad is $5\times4+3=23$; therefore, subtracting 23 from 776, we have 753, which is the year before Christ to which the foundation of Rome is referred by Varro.

2d, When the event took place between the summer solstice and the first of January following, the sum of the Olympic year and of the year before Christ is equal to 777. The difference therefore between 777 and the year in one of the dates will give the year in the other date. Thus, the moon was eclipsed on the 27th of August, a little before midnight, in the year 413 before our era; and it is required to find the corresponding year in the Olympic era. Subtract 413 from 777, the remainder is 364; and 364 divided by four gives 91 without a remainder; consequently the eclipse happened in the fourth year of the ninety-first Olympiad, which is the date to which it is referred by Thucydides.

If the year is after Christ, and the event took place in one of the first six months of the Olympic year, that is to say, between July and January, we must subtract 776 from the number of the Olympic year to find the corresponding year of our era; but if it took place in one of the last six months of the Olympic year, or between January and July, we must deduct 777. The computation by Olympiads seldom occurs in historical records after the middle of the fifth century of our era.

The names of the months were different in the different Grecian states. The Attic months, which were the most usual, are as follows:

Hecatombæon.	Gamelion.
Metageitnion.	Anthesterion.
Boedromion.	Elaphebolion.
Pyanepsion.	Munychion.
Mœmacterion.	Thargelion.
Poseideon.	Seirophorion.

Era of the Foundation of Rome.

After the Olympiads, the era most frequently met with in ancient history is that of the foundation of Rome, which is the chronological epoch adopted by all the Roman historians. There are various opinions respecting the year in which this event took place; but the authorities most deserving of credit are the five following:

1st, Fabius Pictor, who places the epoch of the foundation of Rome in the latter half of the first year of the eighth Olympiad, which corresponds with the 3967th of the Julian period, and with the year 747 before Christ.

2d, Polybius, who places it in the second year of the seventh Olympiad, corresponding with 3964 of the Julian period, and 750 B. C.

3d, Cato, who places it in the first year of the seventh Olympiad, that is, in 3963 of the Julian period, and 751 B. C.

4th, Verrius Flaccus, who places it in the fourth year of the sixth Olympiad, that is, in the year 3962 of the Julian period, and 752 B. C.

5th, Terentius Varro, who places it in the third year of the sixth Olympiad, that is, in the year 3961 of the Julian period, and 753 B. C.

A knowledge of these different computations is frequently necessary, in order to reconcile the Roman historians with one another, and even with themselves. Livy in general adheres to the epoch of Cato, though he sometimes follows that of Fabius Pictor. Cicero follows the account of Varro, which is also in general adopted by Pliny. Dionysius of Halicarnassus follows Cato. Modern chronologers for the most part adopt the account of Varro, which is supported by a passage in Censorinus, where it is stated that the 991st year of Rome commenced with the festival of the Palilia, in the consulship of Ulpius and Pontianus. Now this consulship corresponded with the 238th year of our era; therefore, deducting 238 from 991, we have 753 to denote the year before Christ. The Palilia commenced on the 21st of April; all the accounts agree in regarding this date as the epoch of the foundation of Rome.

The Romans employed two sorts of years, the civil year, which was used in the transaction of public and private affairs, and the consular year, according to which the annals of their history have been composed. From the time of Numa the civil year always commenced with the calends of January; but by reason of the arbitrary manner in which, till the time of Julius Cæsar, their calendar was regulated by the pontiffs, the civil months did not retain a fixed place in the solar year, and the calends of January successively passed into the different seasons. Hence part of the Roman civil year corresponded to one Julian year, and part of it to another. Thus, when the 1st of January in the civil year corresponded with the Julian 1st of September, the first four months of the civil year belonged to one Julian year, and the last eight months to the Julian year following. With regard to the consular year (or year of the reign before the expulsion of the kings) the confusion and uncertainty are still greater. The epoch of the succession of a king regulated the commencement of the years of his reign, and the installation of the consuls the commencement of the consular year. The initial day of the consulate was never fixed, at least before the seventh century of Rome, but varied with the different accidents which in times of political commotion so frequently occurred to accelerate or retard the elections. Hence it happens that a consular year, generally speaking, comprehends a part not only of two Julian years, but also of two civil years. The consulate is the date employed by the Latin historians generally, and by many of the Greeks, down to the sixth century of our era.

In the era of Rome the commencement of the year is placed at the 21st of April; an event therefore which happened in the months of January, February, March, or during the first twenty days of April, in the year (for example) 500 of Rome, belongs to the civil year 501. Before the time of the Decemvirs, however, February was the last month of the year. Many authors confound the year of Rome with the civil year, supposing them both to begin on the 1st of January. Others again confound both the year of Rome and the civil year with the Julian year, which in fact became the civil year after the regulation of the calendar by Julius Cæsar. Through a like want of

attention, many writers also, particularly among the moderns, have confounded the Julian and Olympic years, by making an entire Julian year correspond to an entire Olympic year, as if both had commenced at the same epoch. Much attention to these particulars is required in the comparison of ancient dates.

The Christian Era.

The Christian or vulgar era, called also the era of the Incarnation, is now almost universally employed in Christian countries, and is even used by some eastern nations. Its epoch or commencement is the 1st of January in the fourth year of the 194th Olympiad, the 753d from the foundation of Rome, and the 4714th of the Julian period. It is usually supposed to begin with the year of the birth of Christ, but there are various opinions with regard to the year in which that event took place. The most probable is, that the birth of Christ happened five years and seven days before the initial day of the vulgar era. This method of dating the years was introduced into Italy in the sixth century, by Dennis or Dionysius the Little, a Roman abbot, and began to be used in France in the seventh, though it was not generally followed in that country before the reigns of Pepin and Charlemagne. In England it seems to have been introduced by St Augustin. Before its adoption the usual practice in Latin countries was to distinguish the years by their number in the cycle of Indiction.

In the Christian era the years are simply marked and distinguished by the cardinal numbers; those before Christ being distinguished by the characters B. C. (Before Christ), or A. C. (Ante Christum), and those after Christ by A. D. (Anno Domini.) This method of reckoning time is more commodious than those which employ cycles or periods of any length whatever; and, provided the commencement of the era had been placed at the creation of the world, or at some point of time prior to all historical records, it would have satisfied, in the simplest manner possible, all the conditions that are necessary for registering the succession of events. But when the commencement of the era is placed, as in the present case, at an intermediate period of history, some inconvenience is felt with regard to the dates of preceding events, on account of the interruption of the numerical order. Some ambiguity is also occasioned by the want of uniformity in the methods adopted by authors, of numbering the preceding years. In order to preserve uniformity in their computations, astronomers denote the year which preceded the first of our era by 0, and the year previous to that by 1 B. C.; but chronologers, in conformity with common notions, call the year preceding the era 1 B. C., the previous year 2 B. C., and so on. By reckoning in this manner, there is an interruption in the regular succession of the numbers; and in the years preceding the era, the leap years, instead of falling on the fourth, eighth, twelfth, &c., fall, or ought to fall, on the first, fifth, ninth, &c.

In the chronicles of the middle ages much uncertainty frequently arises respecting dates, on account of the different epochs that have been assumed for the commencement of the Christian year. Dennis, the author of the era, thinking it more natural to reckon from the conception, adopted the day of the *Annunciation*, or the 25th of March, which preceded the birth of Christ by nine months, as the commencement of the first year of the era. The epoch of Dennis therefore precedes that of the vulgar era by nine months and seven days. This manner of dating was followed in some of the Italian states, and continued to be used in Pisa even down to the year 1745. It was also adopted by some of the Popes in their Bulls; and there are proofs of its having been employed in France about the middle of the eleventh century. Some chroniclers, who adhere to the day of the annunciation as the commencement of the year, reckon from the 25th of March *following* our epoch, as the Florentines in the tenth century. Gregory of Tours, and some writers of the sixth and seventh centuries, make the year commence sometimes with the 1st of March, like the Romans before the time of Numa, and sometimes with the 1st of January. In France under the third race of kings it was usual to begin the year with Easter; and this practice continued at least till the middle of the sixteenth century, for an edict was passed by Charles IX. in the month of January 1563, ordaining that the commencement of the year should thenceforth be considered as taking place on the first of January. An instance is given, in *l'Art de Verifier les Dates*, of a date in which the year is reckoned from the 18th of March; but it is probable that this refers to the astronomical year, and that the 18th of March was taken for the day of the vernal equinox. In Germany, about the eleventh century, it was usual to commence the year at Christmas; and this practice also prevailed at Milan, Rome, and other Italian cities, in the thirteenth, fourteenth, and fifteenth centuries.

In England, the practice of placing the beginning of the year at Christmas was introduced in the seventh century, and traces of it are found to exist even in the thirteenth. Gervais of Canterbury, who lived in the beginning of the thirteenth century, mentions that almost all writers of his country had agreed in regarding Christmas day as the first of the year, because it forms as it were the term at which the sun finishes and recommences his annual course. In the twelfth century, however, the custom of beginning the civil year with the day of the Annunciation, or the 25th of March, began to prevail, and continued to be generally followed from that time till the reformation of the calendar in 1752. The *historical* year has always been reckoned by English authors to begin with the first of January. The liturgic year of the church of England commences with the first Sunday of Advent.

A knowledge of the different epochs which have been chosen for the commencement of the year in different countries is indispensably necessary to the right interpretation of the ancient chronicles and annals, in which the dates often appear contradictory, though correctly and precisely marked. We may cite an example or two. It is well known that the emperor Charlemagne was crowned at Rome on Christmas-day in the year 800, and that he died in the year 814, according to our present manner of reckoning; but in the annals of Metz and Moissac, the coronation of Charlemagne is stated to have taken place in the year 801, and his death in 813. Both these statements appear at first sight to be erroneous; but on attending to the different periods at which the year has been supposed to begin, they will both be easily reconciled with the known facts. In the first case the annalist supposes the year to begin with Christmas, and accordingly reckons the 25th of December and all the following days of that month to belong to 801, whereas in the common reckoning they would be referred to the year 800. In the second case the year has been supposed to begin with the 25th of March, or perhaps with Easter; consequently the first three months of the year 814, reckoning from the 1st of January, would be referred to the end of the year 813. As another example, the English revolution is popularly called the revolution of 1688. Had the year then begun, as it now does, with the 1st of January, it would have been the revolution of 1689, that event having taken place in February in the year 1689; but at that time the year was considered in England as beginning on the 25th of March. Another circumstance to which it is often necessary to pay attention in the comparison of dates, is the alteration of style which took place on the adoption of the

Gregorian Calendar. The old style still continues to be used by the Russians and Greeks; and in order to convert a date expressed in this manner into the new style, it is necessary to attend to the variation which takes place from century to century, in the interval between the commencement of the Julian and Gregorian years. From the reformation of the calendar in 1582 to the 29th of February 1700, the difference is ten days; from the 1st of March 1700 to the 29th of February 1800, it is eleven days; from the 1st of March 1800 to the 29th February 1900 the difference is twelve days; and after the 1st of March 1900, if the old style shall then continue to be in use, the difference will be thirteen days, till the 29th of February 2100, as has been explained at length in the article CALENDAR.

Era of the Creation of the World.

As the Greek and Roman methods of computing time were connected with certain Pagan rites and observances, which the Christians held in abhorrence, these began at an early period to imitate the Jews in reckoning their years from the creation of the world. The chronological elements on which both Jews and Christians founded their computations for determining the epoch of that event were derived from the Old Testament narrative, which, though sufficiently circumstantial to enable us to determine the lapse of time during the first two ages of the world with considerable precision, has been transmitted to us through three distinct channels, not only differing greatly in respect of chronology, but totally irreconcilable with each other. These are, first, the Hebrew text of the Scriptures; second, the Samaritan text; and, third, the Greek version of the Septuagint. Unfortunately no very conclusive reason can be given for preferring any one of these accounts to another. We have no concurrent testimony with which to compare them: it is not even known which of them was regarded as the most probable by the Jews themselves, when the books of the Old Testament were revised and transcribed by Ezra; and the ordinary rules of probability cannot be applied to a state of things in which the duration of human life extended to nearly a thousand years.

Between the creation and the flood ten patriarchs are enumerated, whose names, with the age of each at the birth of his eldest son, according to the three versions, are as follows:

	Hebrew.	Samaritan.	Septuagint.
Adam	130	130	230
Seth	105	105	205
Enos	90	90	190
Cainan	70	70	170
Mahalaleel	65	65	165
Jared	162	62	162
Enoch	65	65	165
Methusaleh	187	67	187
Lamech	182	53	188
Noah	500	500	500
Total	1556	1207	2162

Noah entered the ark when he was 600 years of age; by adding, therefore, a hundred to each of the above sums, we have for the interval between the creation of Adam and the flood,

	Years.
According to the Hebrew account	1656
According to the Samaritan	1307
According to the Septuagint	2262

Hence it appears that the Greek version assigns to this period a duration of 606 years above the Hebrew account, and 955 above the Samaritan, while the two latter differ from each other only by 349 years. On account of their nearer agreement, and also of their greater antiquity, critics generally give the preference to the Hebrew and Samaritan texts; and as it appears from a passage in St Jerome, that in his day some manuscripts of the Samaritan agreed with the Hebrew in respect of Methusaleh and Lamech (two out of the three cases in which it at present differs), chronologers usually adopt the Hebrew account. The Latin or vulgate translation, which was declared authentic by the Council of Trent, is in entire conformity with the Hebrew.

The second age of the world is reckoned from the deluge to the vocation of Abraham. It contains also ten patriarchs (the Septuagint reckons eleven), with respect to whose ages the three accounts differ still more widely than in the case of the antediluvian patriarchs. The following are their names, with the age of each at the birth of his eldest son:

	Hebrew.	Samaritan.	Septuagint.
Shem	100	100	100
Arphaxad	35	135	135
Cainan II.	—	—	130
Salah	30	130	130
Eber	34	134	134
Peleg	30	130	130
Reu	32	132	132
Serug	30	130	130
Nahor	29	79	179
Terah	70	70	70
Abraham	75	75	75
Total	465	1115	1345

From the above sums we must deduct the age of Shem when the deluge took place. This was ninety-eight years. The interval between the flood and the call of Abraham is consequently,

	Years.
According to the Hebrew account	367
According to the Samaritan	1017
According to the Greek	1243

In this case the Samaritan and Greek accounts differ greatly from the Hebrew. Their difference from each other is only 230 years; and if we reject Cainan II., whose name does not appear either in the Hebrew or Samaritan text, the difference is only 100 years, which may easily be supposed to have arisen from the errors of the copyists. The near agreement of the Samaritan and Greek accounts renders it probable that the Hebrew text is in error. As another reason for giving the preference to the Samaritan, it may also be mentioned, that according to the Hebrew account, the dispersion of the descendants of Noah, which took place in the time of Peleg, must have happened about a hundred years after the deluge; and it can hardly be conceived that in so short a space of time they should have increased to so great an extent, that, as it is mentioned, a single country could not contain them. According to the Samaritan text, the dispersion took place about 400 years after the deluge,—a space of time which allows of a considerable increase in the number of the inhabitants of the earth.

From this period the intervals of time between the principal events recorded in Scripture are seldom mentioned in the same circumstantial manner; and the chronologers who computed the succession of years had not only to contend with the discordant readings, but were often obliged to assign arbitrary values to the *generations*, or other vague terms by which the time is computed. From computations founded on such loose and uncertain data, it would be in vain to look for agreement; accordingly the results not only present great discrepancies, but

appear to be as numerous as the computations. Desvignoles, in the preface to his Chronology of Sacred History, asserts that he has collected upwards of two hundred different calculations, the shortest of which reckons only 3483 years between the creation of the world and the commencement of the vulgar era, and the longest 6984. The difference amounts to thirty-five centuries. In the following table we have inserted the results obtained by some of the most eminent of the computers. The reader who is desirous of more information on this subject may consult the first volume of the *Universal History*, or *L'Art de Verifier les Dates, avant J. C.* p. ix.

Table of the Years elapsed between Adam and the Birth of Christ, according to the computation of the principal Chronologers.

	Years.
Alphonso X. king of Castile, in the tables of Regiomontanus	6984
Suidas	6000
Nicephoras, patriarch of Constantinople	5700
Riccioli, according to the Septuagint	5634
Clement of Alexandria	5624
The Septuagint of John Ernest Grabe (computation followed by the Russians)	5508
Julius Africanus	5500
The Ethiopians	5499
Albumazar, an Arabian	5328
Eusebius, bishop of Cæsarea	5200
Authors of *L'Art de Verifier les Dates*	4963
Flavius Josephus the historian	4698
Riccioli, according to the Vulgate, 2d System	4184
Michael Mœstlin	4079
Riccioli, 3d System	4062
John Müller, or Regiomontanus	4053
Archbishop Usher, in Moreri	4004
The same, in Chevreau	4000
Kepler, Petau, and Decker	3984
Philip Landsberg	3972
Gerard Mercator and Peter Opmeer	3966
Longomontanus, in the *Astronomia Danica*	3964
John Lightfoot	3960
John Pic, count of Mirandola	3955
Venerable Bede, in Chevreau	3952
Joseph-Juste Scaliger	3950
The same, in Chevreau	3947
St Jerome	3941
Mercator, 2d calculation	3928
James Gordon, a Scotch Jesuit	3880
Some of the Talmudists	3784
The modern Jews	3760
Abridged Chronology of the Jews	3670
Louis Lippoman, a Venetian	3616

All that can be gathered from these conflicting statements amounts to this, that the true epoch of the creation of the world is utterly unknown. British chronologers in general prefer the computation of Archbishop Usher, who places the creation of the world, or rather of Adam, 4004 years before the vulgar era.

Jewish Year and Eras.

Before the departure of the Israelites from Egypt, their year commenced at the autumnal equinox; but in order to solemnize the memory of their deliverance, the month of *Nisan* or *Abib*, in which that event took place, and which falls about the time of the vernal equinox, was afterwards regarded as the beginning of the ecclesiastical or legal year. In civil affairs, and in the regulation of the jubilees and sabbatical years, the Jews still adhere to the ancient year, which begins with the month Tisri, about the time of the autumnal equinox.

The ancient Jewish year was lunisolar, that is to say, the months were regulated by the moon, and intercalations employed to preserve a correspondence between the same months and the same seasons of the year. This correspondence was implied in the ceremonials of their religion. The passover began at the middle of the month Nisan; and, besides the paschal lamb, required the offering of a sheaf of barley as the first fruits of the harvest. Pentecost, or the feast of weeks, which was celebrated fifty days after the passover, required the offering of two loaves as the first fruits of the wheat harvest; and the feast of tabernacles, which was always celebrated on the 15th of the month Tisri, was at the end of the harvest. Hence the passover could only be celebrated about the season when the barley was ready to be cut, Pentecost after the wheat was ripe, and the feast of tabernacles after the vintage and the ingathering of the olives. These regulations rendered it necessary that the three great festivals of the Jews should always occur at nearly the same seasons, and consequently, that some sort of intercalation should be employed for the adjustment of solar and lunar time. But the methods employed for this purpose seem to have been of the rudest kind,—founded on no astronomical calculation, and regulated by no fixed rule. The beginning or end of the month was determined only by sight. When a new moon became visible, a new month began. Experience taught them that it was needless to look out for a new moon before the 29th day of the month; if a new moon then appeared, the next day was the first of the following month; if not, they resumed their watch on the night following, and if the moon was not then visible, they concluded that it must have been obscured by clouds, and the following day was reckoned the first of the succeeding month. Twelve months formed the ordinary year, but every two or three years an intercalary month was added. The rule which they followed with regard to the intercalary month seems to have been this. When the 15th of Nisan, which was the first day of unleavened bread, and of the passover, would have occurred in the ordinary course before the vernal equinox, an intercalary month was inserted before Nisan, in consequence of which the passover, with the feasts depending on it, was thrown back a whole month. The intercalary month was called *ve-Adar*, or second Adar, from its immediately following Adar, the last of the twelve ordinary months.

While the year continued to be regulated in this uncertain and arbitrary manner, it is evident that uniformity could only be preserved by conventional arrangements entered into from year to year. Accordingly the Jews, after their dispersion, were constrained to have recourse to the astronomical rules and cycles of the more enlightened heathen, in order that their religious festivals might be observed on the same days in all the countries through which they were scattered. For this purpose they adopted a cycle of eighty-four years, which is mentioned by several of the ancient fathers of the church, and which the early Christians borrowed from them for the regulation of Easter. This cycle seems to be neither more nor less than the Calippic period of seventy-six years, with the addition of a Greek octaeteris, in order to disguise its true source, and give it an appearance of originality. In fact, the period of Calippus containing 27,759 days, and the octaeteris 2922 days (see CALENDAR), the sum, which is 30,681, is exactly the number of days in eighty-four Julian years. But the addition was very far from being an improvement on the work of Calippus; for instead of a difference of only five hours and fifty-three minutes between the places of the sun and moon, which was the

whole error of the Calippic period, this difference, in the period of eighty-four years, amounted to one day six hours and forty-one minutes. Buccherius places the commencement of this cycle in the year 162 B. C.; Prideaux in the year 291 B. C. According to the account of Prideaux, the fifth cycle must have commenced in the year 46 of our era; and it was in this year, according to St Prosperus, that the Christians began to employ the Jewish cycle of eighty-four years, which they followed, though not uniformly, for the regulation of Easter, till the time of the council of Nice.

Soon after the Nicene council, the Jews, in imitation of the Christians, abandoned the cycle of eighty-four years, and adopted that of Meton, by which their lunisolar year is regulated at the present day. This improvement was first proposed by Rabbi Samuel, rector of the Jewish school of Sora in Mesopotamia, and was finally accomplished in the year 360 of our era by Rabbi Hillel, who introduced that form of the year which the Jews at present follow, and which, they say, is to endure till the coming of the Messiah.

The following are the names of the Jewish months, with the number of days in each:

	Days.		Days.
1. Nisan, or Abib	30	7. Tisri	30
2. Jyar, or Zius	29	8. Marchesvan	29 or 30
3. Sivan	30	9. Chisleu	29 or 30
4. Thammuz	29	10. Thebet	29
5. Ab	30	11. Sebat	30
6. Elul	29	12. Adar	29
and, in intercalary years, Ve-Adar			30

When each of the two months Marchesvan and Chisleu has twenty-nine days, the year of twelve months contains only 353 days, and is called *defective;* when these months contain each thirty days, the year contains 355 days, and is called *perfect;* when the one contains twenty-nine days and the other thirty, the year is *common*, and contains 354 days. These two months are variable, because certain days of the week are regarded by the Jews as unlucky; on such days it is not lawful to celebrate the feasts; and as the passover begins on the same day of the week as that with which the year began, when the first day of the year would fall, in the regular course, on one of the unlucky days, the commencement of the year is postponed to the day following.

Till the fifteenth century the Jews usually followed the era of the Seleucidæ or of Contracts. Since that time they generally employ a mundane era, and date from the creation of the world, which, according to their computation, took place 3760 years and about three months before the commencement of our era. No rule can be given for determining with certainty the day on which any given Jewish year begins, without entering into the minutiæ of their irregular and complicated calendar.

Egyptian Year and Canicular Period.

The ancient year of the Egyptians appears to have been lunisolar, and to have continued so till the reign of Hyperion or Osiris. From that time they employed a solar year, which consisted of 365 days, or twelve months of thirty days each, with five complementary days added at the end of the last month. This was their religious year; and as its commencement anticipated that of the true solar year by one day every four years, it was adhered to long after they had discovered that the year consists of $365\frac{1}{4}$ days, from superstitious notions, in order that each of the seasons might in its turn be blessed by the enjoyment of the sacred festivals.

As the anticipation of a day every four years brought back the commencement of the vague year to the same place in the seasons in the space of 1461 years, it follows that 1461 Egyptian years are equal to 1460 Julian years. The period of 1461 Egyptian years is denominated in chronology the *Sothic* or *Canicular* period, because it commenced with the heliacal rising of the dog-star, called in Egypt Sothis; that is to say, it commenced at the time when that star begins to disengage itself from the rays of the sun, and to be visible just before sunrise. In the latitude of Lower Egypt the dog-star begins to rise heliacally about the 20th of July.

The vague year of the Egyptians began with the month of Thoth, or the 20th of July, in the year of our era 136, which year, therefore, was the first of a Sothic period. The same coincidence took place 1460 Julian years before that time, that is to say, in the year 1325 before Christ. The cycle which began 1325 B. C. is regarded by chronologers as the second which was used in Egypt. Hence, since $1325+1460=2785$, the first must have commenced in the year 2785 B. C. according to the Julian computation. In this first cycle we must place the principal events of Egyptian history, such as the invasion of the shepherds, the establishment of the Israelites in that kingdom, &c.

The names of the Egyptian months are,

1. Thoth.	7. Phamenoth.
2. Paophi.	8. Pharmuthi.
3. Athyr.	9. Pashon.
4. Cohiac.	10. Payni.
5. Tybi.	11. Epiphi.
6. Meshir.	12. Mesori.

Each month contained thirty days, and the year, as already stated, was completed by the addition of five supplementary or epagomenal days.

Era of Constantinople.

This era, which is still used in the Greek church, and was followed by the Russians till the time of Peter the Great, dates from the creation of the world. The incarnation falls in the year 5509, and corresponds, as in our era, with the fourth year of the 194th Olympiad. The civil year commences with the 1st of September; the ecclesiastical year sometimes with the 21st of March, sometimes with the 1st of April. It is not certain whether the year was considered at Constantinople as beginning with September previous to the separation of the Eastern and Western empires.

At the commencement of our era there had elapsed 5508 years and four months of the era of Constantinople. Hence the first eight months of the Christian year 1 coincide with the Constantinopolitan year 5509, while the last four months belong to the year 5510. In order, therefore, to find the year of Christ corresponding to any given year in the era of Constantinople, we have the following rule: If the event took place between the 1st of January and the end of August, subtract 5508 from the given year; but if it happened between the 1st of September and the end of the year, subtract 5509.

Era of Alexandria.

The chronological computation of Julius Africanus was adopted by the Christians of Alexandria, who accordingly reckoned 5500 years from the creation of Adam to the birth of Christ; but in reducing Alexandrian dates to the common era, it must be observed that Julius Africanus placed the epoch of the Incarnation three years earlier than it is placed in the usual reckoning, so that the initial day of the Christian era fell in the year 5503 of the Alexandrian era. This correspondence, however, continued only from the introduction of the era till the accession of Diocletian, when an alteration was made by dropping ten years in the Alexandrian account. Diocletian ascended the throne

of the Roman empire in the year of Christ 284. According to the Alexandrian computation, this was the year 5787 of the world, and 287 of the incarnation; but on this occasion ten years were omitted, and that year was thenceforth called the year 5777 of the world, and 277 of the Incarnation. There are, consequently, two distinct eras of Alexandria, the one being used before, and the other after the accession of Diocletian. It is not very well known for what reason the alteration was made; but it is conjectured that it was for the purpose of causing a new revolution of the cycle of nineteen years (which was introduced into the ecclesiastical computation about this time by Anatolius, bishop of Hierapolis) to commence with the first year of the reign of Diocletian. In fact, 5777 being divided by 19, leaves 1 for the year of the cycle. The Alexandrian era continued to be followed by the Copts in the fifteenth century, and is said to be still used in Abyssinia.

Dates expressed according to this era are reduced to the common era by subtracting 5502, till the Alexandrian year 5786 inclusive, and after that year by subtracting 5492; but if the date belongs to one of the four last months of the Christian year, we must subtract 5503 till the year 5786, and 5493 after that year.

Mundane Era of Antioch.

The chronological reckoning of Julius Africanus formed also the basis of the era of Antioch, which was adopted by the Christians of Syria, at the instance of Panodorus, an Egyptian monk, who flourished about the beginning of the fourth century. Panodorus struck off ten years from the account of Julius Africanus with regard to the years of the world, and he placed the Incarnation three years later, referring it to the fourth year of the 194th Olympiad, as in the common era. Hence the era of Antioch differed from the original era of Alexandria by ten years; but after the alteration of the latter at the accession of Diocletian, the two eras coincided. In reckoning from the Incarnation, however, there is a difference of seven years, that epoch being placed in the reformed era of Alexandria, seven years later than in the mundane era of Antioch or in the Christian era.

As the Syrian year began in autumn, the year of Christ corresponding to any year in the mundane era of Antioch is found by subtracting 5492 if the event falls between January and September; from September to January subtract 5493.

Era of Nabonassar.

This era is famous in astronomy, having been generally followed by Hipparchus and Ptolemy. It had been in use for some centuries among the Chaldean astronomers; for the ancient observations of eclipses, which were collected in Chaldea by Callisthenes, the general of Alexander, and transmitted by him into Greece to Aristotle, were for the greater part referred to the commencement of the reign of Nabonassar, founder of the kingdom of the Babylonians. The epoch from which it is reckoned is precisely determined by numerous celestial phenomena recorded by Ptolemy, and corresponds to Wednesday at mid-day, the 26th of February of the year 747 before Christ. The year consisted of twelve months of thirty days each, with five complementary days added at the end. No intercalation was used; and it is therefore in all respects the same as the ancient Egyptian year. From this circumstance the initial day of the year falls one day earlier every four years than the first of the Julian year; so that 1460 Julian years are equal to 1461 Babylonian years. On account of this difference in the length of the year, the conversion of dates according to the era of Nabonassar, into years before Christ, is attended with considerable trouble. The surest way is to follow a comparative table. Frequently the year cannot be fixed with certainty, unless we also know the month and the day.

The Greeks of Alexandria formerly employed the era of Nabonassar, with a year of 365 days; but soon after the reformation of the calendar by Julius Cæsar, they adopted, like the other Roman provincials, the Julian intercalation. At this time the first of Thoth had receded to the 29th of August. In the year 136 of our era, the first of Thoth, in the ancient Egyptian year, corresponded with the 20th of July, between which and the 29th of August there are forty days. The adoption of the Julian year must therefore have taken place about 160 years before the year 136 of our era (the difference between the Egyptian and Julian years being one day in four years), that is to say, about the year 25 B. C. In fact, the first of Thoth corresponded with the 29th of August in the Julian calendar, in the years 25, 24, 23, and 22 B. C.

Era of the Seleucidæ, or Macedonian Era.

The era of the Seleucidæ dates from the epoch of the first conquests of Seleucus Nicator in Syria, 311 years before Christ, in the year of Rome 442, and twelve years after the death of Alexander the Great. It was adopted not only in the monarchy of the Seleucidæ, but in general in all the Greek countries bordering on the Levant; was followed by the Jews till the fifteenth century; and is said to be used by some Arabians even at the present day. By the Jews it was called the *Era of Contracts;* by the writers of the books of Maccabees the *Era of Kings.* But notwithstanding its general prevalence in the East during a great number of centuries, the authors by whom it was followed differ much with regard to their manner of expressing dates, in consequence of the different epochs which they adopt for the commencement of the year. Among the Syrian Greeks the year began with the month Elul, which corresponds to our September. The Nestorians and Jacobites at the present day suppose it to begin with the following month, or October. The author of the first book of Maccabees makes the era commence with the month Nisan, or April; and the author of the second book with the first Tishrin, or October. Albategnius, a celebrated Arabian astronomer, dates from the 1st of October. Some of the Arabian writers, as Alfragan, date from the 1st of September. At Tyre the year was counted from the 19th of our October, at Gaza from the 28th of the same month, and at Damascus from the vernal equinox. These discrepancies with respect to the initial day of the year render it extremely difficult to determine the exact correspondence of Macedonian dates with those of other eras; and the difficulty is rendered still greater by the want of uniformity in respect of the length of the year. Some authors who follow the Macedonian era, use the Egyptian or vague year of 365 days; Albategnius adopts the Julian year of $365\frac{1}{4}$ days. For all these reasons, it frequently happens that the date cannot be fixed, unless some other chronological characters are given with it than merely the month and the year.

According to the computation most generally followed, the year 312 of the era of the Seleucidæ began on the 1st of September in the Julian year preceding the first of our era. Hence, to reduce a Macedonian date to the common era, subtract 311 years and four months.

The names of the Syrian and Macedonian months, and their correspondence with the Roman months, are as follows:

Syrian.	Macedonian.	English.
Elul.	Gorpiæus.	September.
Tishrin I.	Hyperberetæus.	October

Syrian.	Macedonian.	English.
Tishrin II.	Dius.	November.
Canun I.	Apellæus.	December.
Canun II.	Audynæus.	January.
Sabat.	Peritius.	February.
Adar.	Dystrus.	March.
Nisan.	Xanticus.	April.
Jiar.	Artemisius.	May.
Haziran.	Dæsius.	June.
Tamus.	Panæmus.	July.
Ab.	Lous.	August.

Era of Alexander.

Some of the Greek historians have assumed as a chronological epoch the death of Alexander the Great, which took place in the year 325 before Christ. The year is the same as in the preceding era. This era has not been much followed; but it requires to be noticed in order that it may not be confounded with the era of the Seleucidæ.

Era of Tyre.

The era of Tyre is reckoned from the 19th of October, or the beginning of the Macedonian month Hyperberetæus, in the year 126 before Christ. In order, therefore, to reduce it to the common era, subtract 125; and when the date is B. C., subtract it from 126. Dates expressed according to this era occur only on a few medals, and in the acts of certain councils.

Cæsarean Era of Antioch.

This era was established to commemorate the victory obtained by Julius Cæsar on the plains of Pharsalia, on the 9th of August in the year 48 B. C., and the 706th of Rome. The Syrians computed it from their month Tishrin I.; but the Greeks threw it back to the month Gorpiæus of the preceding year. Hence there is a difference of eleven months between the epochs assumed by the Syrians and Greeks. According to the computation of the Greeks, the 49th year of the Cæsarean era began in the autumn of the year preceding our history; and, according to the Syrians, the 49th year began in the autumn of the first year of the Incarnation. It is followed by Evagrius in his Ecclesiastical History.

Julian Era.

The Julian era commences with the 1st of January, forty-five years before Christ. It was designed to commemorate the reformation of the Roman calendar by Julius Cæsar.

Era of Spain.

The conquest of Spain by Augustus, which was completed in the thirty-ninth year before Christ, gave rise to another era, which began with the first day of the following year, and was long followed in Spain and Portugal, and generally in all the Roman provinces subdued by the Visigoths, both in Africa and the South of France. Several of the councils of Carthage, and also that of Arles, are dated according to this era. After the ninth century it became usual to join with it the year of the Incarnation in public acts. It was followed in Catalonia till the year 1180, in the kingdom of Arragon till 1350, in Valencia till 1358, and in Castile till 1393. In Portugal it is said to have been in use so late as the year 1415, or 1422, though it would seem, that after the establishment of the Portuguese monarchy, no other era was used in the public acts of that country than that of the Incarnation. As the era of Spain commenced with the 1st of January, and the months and days of the year are those of the Julian calendar, any date is reduced to the common era by subtracting thirty-eight from the number of the year.

Era of Actium.

This era was established to commemorate the battle of Actium, which was fought on the 3d of September, in the year 31 before Christ, and in the 15th of the Julian era. By the Romans the era of Actium was considered as commencing on the 1st of January of the 16th of the Julian era, and the 30th B. C. The Egyptians, who followed it till the time of Diocletian, dated its commencement from the beginning of their month Thoth, or the 29th of August; and the eastern Greeks from the 2d of September. By the latter it was also called the era of Antioch, and continued to be used till the ninth century. It must not be confounded with the Cæsarean era of Antioch, which began seventeen years earlier. Many of the medals struck by the city of Antioch in honour of Augustus are dated according to this era. Besides the era of Actium, there was also an Augustan era, which commenced four years later, or 27 B. C., the year in which Augustus prevailed on the senate and people of Rome to decree him the title of Augustus, and confirm him in the supreme power of the empire.

Era of Diocletian, or Era of Martyrs.

We have already remarked that the Alexandrians, at the accession of Diocletian to the throne of the Roman empire, made an alteration in their mundane era, by striking off ten years from their reckoning. The same event furnished them with an opportunity of establishing a new era, which is still followed by the Abyssinians and Copts. It commences with the 29th of August (the first day of the Egyptian year) of the year 284 of our era, which was the first of the reign of Diocletian. The denomination of *Era of Martyrs*, subsequently given to it in commemoration of the persecution raised by that prince against the Christians, would seem to imply that its commencement ought to be referred to the year 303 of our era; for it was in this year that Diocletian issued his famous edict; but the practice of dating from the accession of Diocletian has prevailed. In order to transfer a date from this era to that of the Incarnation, it is necessary to recollect the form of the Egyptian year. The ancient Egyptian year consisted of 365 days; but after the introduction of the Julian calendar, the astronomers of Alexandria adopted an intercalary year, and added six additional days instead of five to the end of the last month of every fourth year. In consequence of this regulation the year is exactly similar to the Julian year. The Egyptian intercalary year, however, does not correspond to the Julian leap year, but is the year immediately preceding; and the intercalation takes place at the end of the year, or on the 29th of August. Hence the first three years of the Egyptian intercalary period commence on the 29th of our August, and the fourth commences on the 30th of that month. Before the end of that year the Julian intercalation takes place, and the beginning of the following Egyptian year is restored to the 29th of August. Hence, to reduce a date according to this era to our own reckoning, it is necessary, for common years, to add 283 years and 240 days; but if the date belongs to the first three months of the year following the intercalation, or, which is the same thing, if it falls between the 30th of August and the end of the year of the third year of the Julian cycle, we must add 283 years and 241 days. We ought to remark, that the Ethiopians do not reckon the years from the beginning of the era in a consecutive series, but employ a period of 532 years, after the expiration of which they again commence with unity. This is the *Dionysian*, or Great Paschal Period, and is formed

by the multiplication of the numbers 28 and 19, that is, of the solar and lunar cycles, into each other.

The following are the Ethiopian or Abyssinian months, with the days on which they begin in the Julian calendar, or old style:—

Mascaram...29th August.	Magabit.....25th February.
Tikmith.....28th September.	Miazia......27th March.
Hadar.......28th October.	Gimbot......26th April.
Tacsam......27th November.	Sene..........26th May.
Tir...........27th December.	Hamle......25th June.
Yacatit......26th January.	Nahasse.....25th July.

The additional or epagomenal days begin on the 24th of August. In intercalary years the first seven months commence one day later. The Egyptian months, followed by the modern Copts, agree with the above in every respect excepting the names.

Indiction.

The cycle of indiction is a period of fifteen years, and was very generally followed in the Roman empire for some ages before the adoption of the Christian era. We are unacquainted with the circumstances and the exact time of its origin, but it was certainly not in use before the time of Constantine; and examples occur in the Theodosian code of its being employed in dating the years under the reign of Constance, who died 361 A. C. Three *indictions* may be distinguished; but they differ only in regard to the commencement of the year.

1. The *Constantinopolitan Indiction*, which, like the Grecian year, commenced with the month of September. This was followed in the Eastern empire, and in some instances also in France.

2. The *Imperial* or *Constantinian Indiction*, so called because its establishment is attributed to Constantine. This was also called the *Cæsarean Indiction*. It commences on the 24th of September, and it is not unfrequently met with in the ancient chronicles of France and England.

3. The *Roman* or *Pontifical Indiction*, which began on the 25th of December or 1st of January, according as the Christian year was held to commence on the one or other of these days. It is often employed in the papal bulls, especially after the time of Gregory VII.; and traces of its use are found in some of the old French authors.

The first year of the first cycle of Indiction is generally considered to correspond with the year 313 of the Christian era. Some authors, however, regard it as having commenced in 312, others in 314, and some also in 315. The number of cycles, however, is scarcely ever referred to, but only the year in the cycle. Reckoning backwards from 313, the first year of our era is found to be 4 in the cycle of Indiction. Hence to find the Indiction corresponding to any year of the Christian era, add 3 to the date, divide the sum by 15, and the remainder is the Indiction. If there is no remainder, the proposed year is the 15th or last of the cycle.

Era of the Armenians.

The epoch of the Armenian era is that of the council of Tiben, in which the Armenians consummated their schism from the Greek church by condemning the acts of the council of Chalcedon; and it corresponds to Tuesday the 9th of July of the year 552 of the Incarnation. In their civil affairs the Armenians follow the ancient vague year of the Egyptians; but their ecclesiastical year, which begins on the 11th of August, is regulated in the same manner as the Julian year, every fourth year consisting of 366 days, so that Easter and the other festivals are retained at the same place in the seasons as well as in the civil year. The Armenians also make use of the mundane era of Constantinople, and sometimes conjoin both methods of computation in the same documents. In their correspondence and transactions with Europeans, they generally follow the era of the Incarnation, and adopt the Julian year.

To reduce the civil dates of the Armenians to the Christian era, we may proceed as follows. Since the epoch is the 9th of July, there were 176 days from the beginning of the Armenian era to the end of the year 552 of our era; and since 552 was a leap year, the year 553 began a Julian intercalary period. Multiply, therefore, the number of Armenian years elapsed by 365; add the number of days from the commencement of the current year to the given date; subtract 176 from the sum, and the remainder will be the number of days from the 1st of January 553 to the given date. This number of days being reduced to Julian years, add the result to 552, and the sum gives the day in the Julian year, or old style.

In the ecclesiastical reckoning the year begins on the 11th of August. To reduce a date expressed in this reckoning to the Julian date, add 521 years, and the days elapsed from the 1st of January to the 10th of August, both inclusive, of the year 552; that is to say (since 552 is a leap year), 223 days. In leap years, one day must be subtracted if the date falls between the 1st of March and 10th of August.

The following are the Armenian ecclesiastical months, with their correspondence with those of the Julian calendar:—

1. Navazardi begins.........	11th August.
2. Hori	10th Septembe
3. Sahomi	10th October.
4. Dre Thari...................	9th November.
5. Kagoths	9th December.
6. Aracz	8th January.
7. Malegi	7th February.
8. Arcki	9th March.
9. Angi..........................	8th April.
10. Mariri	8th May.
11. Marcacz	7th June.
12. Herodiez.....................	7th July.

To complete the year, five complementary days are added in common years, and six in leap years.

Era of the Hegira.

The epoch of this era, which is universally used in all Mahommedan countries, is Friday the 16th of July, A. D. 622—the day on which Mahommed fled from Mecca to Medina. Some chronologers, however, and the Arabian astronomers in general, refer its commencement to the preceding day; but though the flight of Mahommed probably began on the evening of Thursday the 15th of July, it is certain, from the comparison of modern dates, that the present practice of the Mahommedans, in dating their civil transactions, is to count from Friday the 16th of July 622. It may be remarked that the civil day of the Mahommedans begins at sunset; the astronomers probably began the day at noon.

The Mahommedan year is strictly lunar, and the civil months are adjusted to the course of the moon, by means of a cycle of 30 years, containing 19 common years of 354 days, and 11 intercalary years of 355 days; whence the cycle contains 10,631 days, which amount to 29 Julian years and 39 days. Each year is divided into 12 months, containing alternately 30 and 29 days, excepting that the last month of the intercalary year contains also 30 days.

The intercalary years are the 2d, 5th, 7th, 10th, 13th, 16th, 18th, 21st, 24th, 26th, and 29th of the cycle.

The names of the Turkish months, with the number of days in each, are as follows:—

	Days.		Days.
Moharem	30	Regeb	30
Saphar	29	Shaban	29
Rabiu I.	30	Ramadan	30
Rabiu II.	29	Shawall	29
Jomadhi I.	30	Dhu'l kadah	30
Jomadhi II.	29	Dhu'l hajjah	29, and in intercalary years 30

The months of the Hegira are composed of weeks of seven days. The following are the names of the days in Turkish and modern Arabic:—

	Turkish.	Modern Arabic.
Sunday	Pazar gun	Yom el-Ahad.
Monday	Pazar ertesi	Yom el-Thena.
Tuesday	Sale	Yom el-Thaleth.
Wednesday	Charshambe	Yom el-Arba.
Thursday	Pershambe	Yom el-Khamis.
Friday	Juma, or Adina	Yom el-Juma.
Saturday	Juma ertesi	Yom el-Effabt.

Such are the chronological elements by means of which Mahommedan dates are reduced to the Christian era. As the rules generally given for this purpose are attended with ambiguity, and cannot be depended on to a day, unless corrected by means of a subsidiary table, we will explain at length a method of proceeding by which the correspondence between the two eras is established, without the slightest risk of ambiguity or mistake. The subject is of some interest, in consequence of the era of the Hegira being used over so large a portion of the world.

Having given a Mahommedan date to find the corresponding date in the Christian era,

1. Divide the number of years elapsed by 30; the quotient will be the number of cycles, and the remainder the number of years elapsed since the beginning of the current cycle. Call the quotient A, and the remainder B; and let x be the number of intercalary years in B. Then the number of days that have elapsed from the commencement of the Hegira to the beginning of the year in which the date occurs, is given by the formula,

$$10631\ A + 354\ B + x;$$

for 10,631 is the number of days in the cycle or intercalary period, and 354 is the number of days in the common lunar year. To the sum obtained from this formula add the days since the beginning of the current year, and the result is the number of days from the commencement of the cycle to the given date.

2. To the number of days from the commencement of the Hegira to the given date, add the number of days between the commencement of our era and the Hegira, and the sum is the number of days from the epoch of the Incarnation to the given date. The number of days from the beginning of our era to the beginning of the Hegira is 22,7016; for .... $621 \times 365 = 226665$

for	$621 \times 365 = 226665$
in 621 years there are 155 leap years	155
from 1st of January to 15th July 622, inclusive	196
Sum	227016

3. It now remains only to reduce the sum thus obtained to Julian years. For this purpose divide by 1461 (the number of days in the Julian intercalary period), and call the quotient C. Divide the remainder by 365, and call the quotient D, and the last remainder y. Then 4 C + D is the number of years elapsed since the beginning of the era, and y is the days elapsed of the current year.

Example.—The treaty of peace concluded between the emperor Charles VI. and Gianihi-Ali Pacha, ambassador of the sultan of Constantinople, is dated the 15th of Rabiu I., in the year of the Hegira 1153; required the year, month, and day, in the Christian era.

1. In this case the years elapsed are 1152; therefore,

$$\begin{array}{r} 30)1152(38 = A. \\ 90 \\ \hline 252 \\ 240 \\ \hline 12 = B. \end{array}$$

The intercalary years being the second, fifth, seventh, tenth, thirteenth, &c., the remainder, 12, contains four intercalary years, whence $x = 4$; therefore

$$\begin{array}{rcrcr} 10631\ A & = & 10631 \times 38 & = & 403978 \\ 354\ B & = & 354 \times 12 & = & 4248 \\ x & = & & & 4 \\ \hline & & & & 408230 \end{array}$$

Add days from first of Moharem to 15th Rabiu I.	74
Days from the beginning of the Hegira	408304
2. Add	227016
From beginning of our era to the given date	635320

3. To convert this sum into Julian years;

$$\begin{array}{r} 1461)635320(434 = C \\ 5844 \\ \hline 5092 \\ 4383 \\ \hline 7090 \\ 5844 \\ \hline 365)1246(3 = D \\ 1095 \\ \hline 151 \quad = y \end{array}$$

$$4\ C + D = 4 \times 434 + 3 = 1739.$$

Therefore, as 1739 years have elapsed, the date required is the 151st day of the Christian year 1740. Now since 1740 is a leap year, the 151st day is the 30th of May. This, however, is in Old Style. Add eleven days for the change of style, and we have the 10th of June.

It results, therefore, that the 15th of Rabiu I. of the year of the Hegira 1153 corresponds with the 10th of June 1740 New Style. In this way any Mahommedan date may be reduced to the corresponding Christian date. The arithmetical operation is extremely simple, and can never lead to ambiguity or error.

Era of Yezdegird, or Gelalæan Era.

This era commences with the elevation of Yezdegird III. to the throne of Persia, and dates from the 16th of June in the year of our era 632. Till the year 1075 A. C. the Persian year resembled that of the ancient Egyptians, consisting of 365 days without intercalation; but at that time the Persian calendar was reformed by Gelal-Edin Malek Schah, sultan of Khorasan, and a method of intercalation adopted, which, though less convenient, is considerably more accurate than the Julian. The intercalary period is 33 years; one day being added to the common year seven times successively at the end of four years, and

the eighth intercalation being deferred till the end of the fifth year (See CALENDAR). This era was at one period universally adopted in Persia, and it still continues to be followed by the Parsees of India. The months consist of thirty days each, and each day is distinguished by a different name. According to Alfragan, the names of the Persian months are as follows:

Afrudin-meh.	Merded-meh.	Adar-meh.
Ardisascht-meh.	Schaharir-meh.	Di-meh.
Cardi-meh.	Mahar-meh.	Behen-meh.
Tir-meh.	Aben-meh.	Affirer-meh.

The five additional days (in intercalary years six) are named *Musteraca.*

As it does not appear that the above-mentioned rule of intercalation was ever regularly followed, it is impossible to assign exactly the days on which the different years begin. In some provinces of India the Parsees begin the year with September, in others they begin it with October. We have stated that the era began with the 16th June 632. But the vague year, which was followed till 1075, anticipated the Julian year by one day every four years. In 443 years the anticipation would amount to about 112 days, and the beginning of the year would, in consequence, be thrown back to near the beginning of the Julian year 632. To the year of the Persian era, therefore, add 631, and the sum will be the year of our era in which the Persian year begins.

Chinese Chronology.

From the time of the emperor Yao, upwards of 2000 years B. C., the Chinese had two different years; a civil year, which was regulated by the moon, and an astronomical year, which was solar. The civil year consisted in general of twelve months or lunations, but occasionally a thirteenth was added, in order to preserve its correspondence with the solar year. Even at this early period the solar or astronomical year consisted of $365\frac{1}{4}$ days, like our Julian year; and it was arranged in the same manner, a day being intercalated every fourth year.

According to the missionary Gaubil, the Chinese divided the day into 100 *ke*, each *ke* into 100 minutes, and each minute into 100 seconds. This practice continued to prevail till the 17th century, when, at the instance of the Jesuit Schaall, president of the tribunal of mathematics, they adopted the European method of dividing the day into twenty-four hours, each hour into sixty minutes, and each minute into sixty seconds. The civil day commences at midnight, and ends at the midnight following.

Since the accession of the emperors of the Han dynasty, 205 B. C., the civil year of the Chinese has begun with the first day of that moon in the course of which the sun enters into the sign of the zodiac which corresponds with our sign Pisces. From the same period also, they have employed, in the adjustment of their solar and lunar years, a period of nineteen years, twelve of which are common, containing twelve lunations each, and the remaining seven intercalary, containing thirteen lunations. It is, however, not precisely known how they distributed their months of thirty and twenty-nine days, or, as they termed them, *great* and *small* moons. This, with other matters appertaining to the calendar, was probably left to be regulated from time to time by the mathematical tribunal.

The Chinese divide the time of a complete revolution of the sun, with regard to the solstitial points, into twelve equal portions, each corresponding to thirty days, ten hours, thirty minutes. Each of these periods, which is denominated a *tze,* is subdivided into two equal portions, called *tchong-ki* and *tsie-ki;* the *tchong-ki* denoting the first half of the *tze,* and the *tsie-ki* the latter half. Though the *tze* are thus strictly portions of solar time, yet, what is remarkable, though not peculiar to China, they give their name to the lunar months, each month or lunation having the name of the *tchong-ki* or sign at which the sun arrives during that month. As the *tze* is longer than a synodic revolution of the moon, the sun cannot arrive twice at a *tchong-ki* during the same lunation; and as there are only twelve *tze,* the year can contain only twelve months having different names. It must happen sometimes that in the course of a lunation the sun enters into no new sign; in this case the month is intercalary, and called by the same name as the preceding month.

For chronological purposes, the Chinese, in common with some other nations of the east of Asia, employ cycles of sixty, by means of which they reckon their days, moons, and years. The days are distributed in the calendar into cycles of sixty, in the same manner as ours are distributed into weeks, or cycles of seven. Each day of the cycle has a particular name; and as it is a usual practice, in mentioning dates, to give the name of the day along with that of the moon and the year, this arrangement affords great facilities in verifying the epochs of Chinese chronology. The order of the days in the cycle is never interrupted by any intercalations that may be necessary for adjusting the months or years. The moons of the civil year are also distinguished by their place in the cycle of sixty; and as the intercalary moons are not reckoned, for the reason before stated, namely, that during one of these lunations the sun enters into no new sign, there are only twelve regular moons in a year, so that the cycle is renewed every five years. Thus the first moon of the year 1833 being the first of a new cycle, the first moon of every sixth year, reckoned backwards or forwards from that date, as 1828, 1823, &c., or 1837, 1842, &c., will also commence a new lunar cycle of sixty moons. In regard to the years, the arrangement is exactly the same. Each has a distinct number or name which marks its place in the cycle, and as this is generally given in referring to dates, along with the other chronological characters of the year, the ambiguity which arises from following a fluctuating or uncertain epoch is entirely obviated. The present cycle began in the year 1804 of our era; the year 1832 is consequently the 29th of the current cycle.

The cycle of sixty is formed of two subordinate cycles or series of characters, one of ten and the other of twelve, which are joined together so as to afford sixty different combinations. The names of the characters in the cycle of ten, which are called *celestial signs,* are,

1. Kea; 2. Yich; 3. Ping; 4. Ting; 5. Woo;
6. Ke; 7. Kang; 8. Sin; 9. Jin; 10. Kwey.

And in the series of 12, denominated *terrestrial* signs,

1. Tse; 2. Tchow; 3. Yin; 4. Maou; 5. Shin; 6. Sze;
7. Woo; 8. We; 9. Shin; 10. Yew; 11. Seo; 12. Hae.

The name of the first year, or of the first day, in the sexagenary cycle, is formed by combining the first words in each of the above series; the second is formed by combining the second of each series, and so on to the tenth. For the next year the first word of the first series is combined with the eleventh of the second; then the second of the first series with the twelfth of the second; after this the third of the first series with the first of the second, and so on till the sixtieth combination, when the last of the first series concurs with the last of the second. Thus Kea-tse is the name of the first year, Yih-tchow that of the second, Kea-seo that of the eleventh, Yih-hae that of the twelfth, Ping-tse that of the thirteenth, and so on. The order of proceeding is obvious.

In the Chinese history translated into the Tartar dialect by the orders of the emperor Kang-hi, who died in 1722, the characters of the cycle begin to appear at the year 2357 B. C. From this it has been inferred, that the

Chinese empire was established previous to that epoch; but it is obviously so easy to extend the cycles backwards indefinitely, that the inference can have very little weight. The characters given to that year 2357 B. C. are Kea-shin, which denote the 41st of the cycle. We must, therefore, suppose the cycle to have begun 2397 B. C., or forty years before the reign of Yao. This is the epoch assumed by the authors of *L'Art de Verifier les Dates*. The mathematical tribunal has, however, from time immemorial, counted the first year of the first cycle from the eighty-first of Yao, that is to say, from the year 2277 B. C.

Since the year 163 B. C. the Chinese writers have generally dated the year from the accession of the reigning emperor. An emperor, on his accession to the throne, gives a name to the years of his reign. He ordains, for example, that they shall be called Ta-te. In consequence of this edict, the following year is called the first of Ta-te, and the succeeding years the second, third, fourth, &c. of Ta-te, and so on, till it pleases the same emperor, or his successor, to ordain that the years shall be called by some other appellation. The periods thus formed are called by the Chinese Nien-hao. According to this method of dating the years, a new era commences with every reign; and the year corresponding to a Chinese date can only be found when we have before us a catalogue of the Nien-hao, with their relation to the years of our era.

The Chinese chronology is discussed with ample detail by Freret, in the *Memoirs of the Academy of Inscriptions*, tom. xviii.; and an abridgment of his memoir is given in *L'Art de Verifier les Dates* (tom. ii. p. 284, *et seq.* Ed. in 4to, 1818), from which the preceding account is principally taken.

Indian Chronology.

The method of dividing and reckoning time followed by the various nations of India resembles in its general features that of the Chinese, but is rendered still more complex by the intermixture of Mahommedan with Hindu customs. Like the Chinese, the Hindus have a solar year, which is generally followed in the transaction of public business, especially since the introduction of European power; and they have also a lunar year, which regulates their religious festivals, and which they follow in their domestic arrangements. Their solar year, or rather sidereal year, is measured by the time in which the sun returns to the same star, and is consequently longer than our astronomical year, by the whole quantity of the precession of the equinoxes. It is reckoned by the Hindus at 365 days, 6 hours, 12 minutes, 30 seconds, and consequently exceeds a Gregorian year by one day in sixty years. The Indian zodiac is divided into twelve solar and twenty-eight lunar signs; and the year begins with the sun's arrival at the first degree of the first sign. The month is the time the sun takes to pass through one sign; and as each sign contains the same number of degrees, the months vary somewhat in length, according as the sun is nearer the apogee or perigee. The longest month may contain 31 days, 14 hours, 39 minutes, and the shortest only 29 days, 8 hours, 21 minutes. The civil months, however, depend solely on the moon; though, with the same perversion of ingenuity which we have already remarked with regard to the Chinese, and of which it would be difficult to find an example, except in the east of Asia, they derive their names from the solar signs of the zodiac. The first civil month commences with the day after the full moon of that lunation in the course of which the sun enters the first Hindu sign, and so on with the others. When the sun enters into no new sign during the course of a lunation, the month is intercalary, and is called by the name of that which precedes or follows it, which some prefix, to distinguish it from the regular month. In some provinces of India, as in Bengal, the civil month commences with the day after the new moon; but in the upper or northern provinces, it begins, as we have stated, with the day after the full moon. From the manner in which they are reckoned, it is evident that the Hindu months, both solar and lunar, neither consist of an entire number of days, nor are regulated by any cycle, but depend solely on the motion of the sun and moon. The time of their commencement is different on every different meridian; and a Hindu has no means of knowing beforehand on what day any month begins, excepting by consulting his almanack. The civil day in all parts of India begins at sunrise.

The Hindu eras have been the subject of much controversy. According to the dreams of Indian mythology, the duration of the world is limited to four *yugs* or ages, three of which have already passed, and the fourth, which is the *kali-yug*, is the last and most deteriorated. It is this only which has any reference to authentic chronology. It forms the principal era of India, and comprehends several others in common use, as the era of Vicramaditya, of Salivahana, the Bengalee era, and the cycle of sixty years.

The *Kali-yug* commenced in the year 3101 B. C. The year is sidereal, and begins when the sun enters the first sign of the Hindu zodiac, which at present happens about the 11th of April. Owing to the precession of the equinoxes, the beginning of the year advances in the seasons at the rate of about one day in sixty years.

The *Era of Vicramaditya* is reckoned from the year 56 B. C., which corresponds to 3045 of the Kali-yug. This era, the years of which are called *Samvat*, prevails chiefly in the higher or northern provinces of India, and in Guzerat. Its name is derived from that of a sovereign of Malwa, who, by defeating Soka, king of Delhi, acquired possession of the principal throne of India. Whether the year from which it is reckoned was that of the accession or death of this prince, is uncertain. The years are reckoned in the same manner as those of the Kali-yug; and it may be remarked of the Indian eras in general, that though some of them profess to be counted from the deaths of their kings, or other historical events, they all commence at the time the sun reaches the same point in his annual course through the zodiac.

The *Era of Salivahana* is the year 78 A. C., which corresponds to 3179 of the Kali-yug, and 134 of the Vicramaditya. The name is derived from Salivahan, who is said to have reigned many years over the kingdom of Norsinga, and to have been a liberal encourager of the arts and sciences. It is generally used in records or writings of importance, but is most prevalent in the southern provinces of Hindustan. The years are called *Saka*.

The *Fuslee Era*, from the near coincidence of its dates with those of the Hegira, seems to have been imposed on the natives of India by their Mahommedan conquerors. It is principally used in revenue transactions, and is pretty generally known over India. There are several eras of this name; but the most common is that which is reckoned from the year 590 A. C. At Madras, the commencement of the Fuslee year is fixed on the 12th of July. In Bengal it begins in September, or with the full moon preceding the autumnal equinox.

The *Bengalee Era* is also supposed to be derived from the Hegira; but the year is measured by solar time, and therefore differs entirely from the Mahommedan year, which is purely lunar. At the present time, the Bengalee epoch is about nine years later than the Hegira; the year 1245 of the Hegira having commenced in July 1829, and the Bengalee year 1236 in April 1829. The sidereal year exceeds the lunar year by 10 days $21\frac{1}{2}$ hours nearly; consequently, by reckoning backwards, it will be found

that the dates of the Bengalee era and of the Hegira coincided about the middle of the sixteenth century. History is silent on the subject; but it seems probable, that though the epoch of the Hegira was partially adopted in India, the Hindus pertinaciously resisted all attempts to disturb their ancient methods of reckoning the subdivisions of the year.

Besides the Indian eras here enumerated, there are some others which are less generally known, or which are followed only in particular provinces. The cycle of sixty years is also sometimes used, particularly in connection with the era of Vicramaditya. According to the Bengal account, the first cycle began 3185 years B. C.; and the year 1832 of our era is consequently the thirty-seventh of the eighty-fourth cycle. In the Telinga account the first cycle began 3114 B. C.; and the year 1832 is the twenty-fourth of the eighty-third cycle.

We will conclude this part of the article with the following table, showing the dates at which the different eras above described respectively commenced.

Julian period began	4713	B. C.
Olympiad of Corœbus	July 776	
Era of Rome, according to Varro	21st April 753	
Jewish era	October 3761	
First Canicular period	2785	
Era of Constantinople	1st September 5509	
Era of Alexandria	5503	
Mundane era of Antioch	September 5493	
Era of Nabonassar	26th February 747	
Era of the Seleucidæ	September 311	
Era of Alexander	September 323	
Era of Tyre	19th October 126	
Cæsarean era of Antioch	October 48	
Julian era	1st January 45	
Era of Spain	1st January 38	
Era of Actium	1st January 30	
Era of Diocletian	29th August 284	A. D.
Era of the Armenians	9th July 552	
Era of the Hegira	16th July 622	
Era of Yezdegird	16th June 632	
First Chinese cycle of sixty years	2277	B. C.
Kali-yug	3101	
Era of Vicramaditya	56	
Era of Salivahana	78	A. D.
Fuslee era	590	
Bengalee era	593	

The utility of chronological and synchronistic tables in the illustration of history has been long perceived. Of the more ancient writers who devoted their labours to this object, the principal are, Diodorus Siculus, Julius Africanus, Eusebius of Cæsarea, and George Syncellus, to whom we are indebted for the preservation of some curious fragments of Berosus, Sanconiathon, and Manetho. The modern works of this kind are exceedingly numerous. It will be sufficient to refer the reader to Petau, *de Doctrina Temporis;* Usher's *Annales Veteris et Novi Testamenti;* Newton's *Chronology;* Blair's *Chronology and History of the World;* Playfair's *Chronology;* and the *Tables Chronologiques de l'Histoire Ancienne et Moderne* of Thouret; without mentioning a multitude of smaller tables, of various degrees of merit. But the most complete work on chronology is the *Art de Verifier les Dates,* an immense compilation, for which the student of history is indebted to the Benedictines of the congregation of St Maur. We may likewise mention, as a very extensive and useful work, though printed in a most inconvenient form, the *Tableaux Historiques Chronologiques et Geographiques* of Buret des Longchamps, the second edition of which was published at Brussels in 1822.

The subjoined table of political events has been compiled with great care for the present edition of the Encyclopædia. Though necessarily of limited extent, it will be found to contain a useful summary of the principal events of ancient and modern history. In the early period, the dates are taken from Usher and Blair, as being those followed by the majority of chronologers. (T. G.)

A CHRONOLOGICAL TABLE *of the Principal Events of Political History, and of the most important Inventions and Discoveries, from the Creation of the World to the Year* 1854.

B. C.

4004 Creation of the World, according to the Hebrew text of the Scriptures.
2349 Commencement of the Deluge.
2200–2100 Kingdoms of Babylon, Assyria, and Egypt, supposed to have been founded respectively by Nimrod, Assur, and Menes.
2089 Kingdom of Sicyon established.
1981 Call of Abraham.
1856 Kingdom of Argos established by Inachus.
1764 Deluge of Ogyges.
1700 The shepherd kings possess Egypt.
1556 Cecrops, first king of Athens.
1503 Deluge of Deucalion.
1493 Cadmus comes into Greece.
1491 The Israelites leave Egypt.
1485 Danaus comes to Greece from Egypt.
1480 Troy built by Dardanus.
1453 The Pentateuch, or five books of Moses, written.
1451 The Israelites enter Canaan.
1406 Minos reigns in Crete; gives laws to the Cretans.
1362 Pelops comes to Greece from Asia.
1352 Corinth said to be founded by Sisyphus.
1344 The kingdom of Mycenæ begins.
1325 Isthmian games instituted.
1294 First colony from Italy to Sicily: second, 1264.
1263 The Argonautic expedition.
1257 Theseus unites the cities of Attica.
1252 Tyre, the capital of Phœnicia, built.
1243 Evander conducts a colony of Greeks into Italy.
1225 to 1215 First and second wars of Thebes.
1193 The Trojan war begins.
1184 Troy taken and burnt by the Greeks.
1104 The Heraclidæ conquer the Peloponnesus.
1102 Sparta becomes a kingdom.
1079 Saul king of Israel.
1070 Athenians abolish regal government. Medon first Archon. Codrus.
1055 David king of Israel.
1044 Migration of the Ionian colonies.

Anglo-French fleet enters the Bosphorus (Oct. 22). Russians occupy the Danubian principalities, and Turks cross the Danube. Disaster at Sinope (Nov. 30).

1854 Alliance concluded between Great Britain, France, and Turkey. Declaration of war between Great Britain and Russia (March 24).

LITERARY CHRONOLOGY.

In the following Table, *b* denotes the year of birth, *d* of death, and *l* an approximation to the medium year of the author's life. The letters immediately following the name denote the country in which the author was born: thus, *R.* stands for *Roman; It.* for *Italian; Ger.* for *German*, &c. Where no indication is given, the country to be supplied is *Greece.*

CHRONOMETER, any instrument for measuring time, as dials, clocks, &c. The term, however, is commonly applied in a restricted sense to a kind of clock so contrived as to measure a small portion of time with great exactness. See CLOCK and WATCH-WORK.

CHRONOMETER is also the name of an instrument invented by Loulie, a French musician, for the purpose of measuring musical time by means of a pendulum. The form of the instrument is described in Malcolm's *Treatise of Music*, p. 407.

The *Metronome*, an instrument of the same kind, was introduced in Austria about the year 1814. It consists of a box containing a pendulum, which has its point of suspension between the extremities of the rod; and attached to the rod there is a sliding weight, by means of which the vibrations may be regulated to any number of beats in a fixed time. The pendulum is set in motion by a simple piece of mechanism, which is wound up like a clock.

CHRUDIM, a town of Bohemia, capital of a cognominal circle, on the right bank of the Chrudimka, an affluent of the Elbe, 58 miles E.S.E. of Prague. The town, which is surrounded by walls, is well built, and has a fine Gothic collegiate church and five others, a Capuchin monastery, high school, and manufactories of calicoes and leather. The horse-markets of Chrudim are much frequented. Pop. 6107.

CHRYSALIS, or AURELIA, the particular form assumed by butterflies, moths, and some other insects, before they arrive at their winged or perfect state. These terms are derived from the golden colour of certain species; though others are green, black, brown, &c. See ENTOMOLOGY, chap. IV.

CHRYSES, the priest of Apollo, and father of Chryseis. When Lyrnessus was taken, and the spoil divided among the conquerors, Chryseis fell to the share of Agamemnon. Chryses went to the Grecian camp to solicit his daughter's restoration; and when his prayers proved fruitless, he implored the aid of Apollo, who visited the Greeks with a plague, and obliged them to restore Chryseïs.

CHRYSIPPUS, a Stoic philosopher, born at Soli in Cilicia. He was a disciple of Cleanthes, successor of Zeno, and wrote many books, several of which related to logic. None of the philosophers dogmatized in stronger terms of the fatal necessity of everything, or declaimed more pompously of the liberty of man, than the Stoics, particularly Chrysippus, who was held of so much importance among them as to give rise to the proverbial remark, that "if Chrysippus had not existed, the Porch could not have been." Yet the Stoics complained, as Cicero relates, that he had collected many arguments in favour of the sceptical hypothesis, which he could not answer himself, and had thus furnished Carneades, their antagonist, with weapons against them. An apophthegm of this philosopher does him honour. Being told that some person spoke ill of him, he said—"It is no matter, I will live so that he shall not be credited."

This was also the name of several ancient physicians; and likewise of a celebrated ecclesiastical writer, about A.D. 450, whose only remaining work, besides some fragments, is a treatise entitled *Homilia de Sancta Deipara*. (Cave, *Hist. Lit.*, vol. i.)

CHRYSOBERYL, a silicious gem, of a pale yellowish-green colour. See MINERALOGY.

CHRYSOLITE (*peridot*, Haüy; *olivin*, Hausmann). When chrysolite is found in a crystallized state, and of considerable dimensions, it is a very beautiful mineral, and presents a fine grass-green colour, with a vitreous fracture, and perfect transparency. Such specimens are very rare, and the locality is quite unknown, but supposed to be Upper Egypt. It occurs also in minute but perfect crystals, along with other gems, in alluvial deposits at Expaillie. It is most commonly found in grains in trap-rocks, sometimes in large spheroidal masses, of an oil-green colour, in a state of granular concretions. It likewise enters into the composition of meteoric stones, and occurs imbedded in the native iron discovered by Pallas in Siberia, and also in the same substance which has subsequently been found at Attacama. Chrysolite is the softest of all gems, being scratched by quartz, and yielding readily to the file. Its specific gravity is 3·4; and, according to Vauquelin, it contains, of silica 38·, magnesia 50·5, and iron 9·5.

CHRYSOLORAS, MANUEL, a learned Greek, who was instrumental in spreading Greek literature in the West. He was born at Constantinople, of a distinguished family, which had removed with Constantine to Byzantium. While still very young, he was sent by the emperor John Palæologus to implore the aid of the Christian princes against the Turks. After an absence of some years, Chrysoloras returned to Constantinople; but at the invitation of the magistrates of Florence he became professor of Greek language in that city about the year 1393, and taught three years. From Florence he passed to Milan; and from Milan to Pavia, at the request of Gian Galeazzo, duke of Milan. On the death of Galeazzo in 1402 he retired to Venice, where he lived several years. He subsequently went to Rome, upon the invitation of Aretino, who had been his disciple, and was then secretary to Gregory XII. In 1408 he was sent to Paris

with an important mission from Manuel Palæologus, the Greek emperor. In 1413 he accompanied cardinals Chalanco and Zabarella on a mission from Pope Martin V. to the emperor Sigismund, to appoint a place of meeting for a general council; and was preparing to go to Constance when he was suddenly cut off, on the 15th of April 1415, in the forty-seventh year of his age. Only two of his works have been printed, viz., his *Erotemata*, or grammatical questions, and *Epistolæ III., de comparatione veteris et novæ Romæ;* but numerous others exist in MS.

CHRYSOPRASE, a name derived from the Greek, and denoting a superior kind of prase. It occurs at Rosemutz in Silesia, and also at New Fane, Vermont, North America. It is of an apple-green colour, more or less intense. It is translucent, with a fine-grained splintery fracture, nearly even, and occurs massive, in contemporaneous veins, traversing rocks of serpentine. Chrysoprase is nearly allied to calcedony; and derives its beautiful colour from an admixture of the oxide of nickel, as ascertained by the analysis of Klaproth.

CHRYSOSTOM, St John (Χρυσόστομος, golden-mouthed), the most famous of the Greek fathers, was born of a noble family at Antioch the capital of Syria, A.D. 347. At the school of Libanius the sophist he gave early indications of his mental powers, and would have been the successor of his heathen master, had he not been stolen away to a life of piety (like Augustin, Gregory of Nazianzen, and Theodoret), by the influence of a pious mother. Immediately after his baptism by Meletius the bishop of Antioch, he gave up all his forensic prospects, and buried himself in an adjacent desert, where for six years he spent a life of ascetic self-denial and study. His infirmities, however, compelled him to return to the world; and the authority of Meletius gained his services to the church. On his arrival he was ordained deacon, and afterwards presbyter at Antioch; and on the death of Nectarius he was appointed archbishop of Constantinople by Eutropius, the favourite minister of the emperor Arcadius. On the archiepiscopal throne Chrysostom still persevered in the practice of monastic simplicity. The ample revenues which his predecessors had consumed in pomp and luxury, he diligently applied to the establishment of hospitals; and the multitudes who were supported by his charity preferred the eloquent discourses of their benefactor to the amusements of the theatre or of the circus. His homilies, which are still preserved, furnish ample apology for the partiality of the people, exhibiting the free command of an elegant and copious language, an inexhaustible fund of metaphors and similitudes, giving variety and grace to the most familiar topics, with an almost dramatic exposure of the folly and turpitude of vice. His zeal as a bishop, and eloquence as a preacher, however, gained him enemies both in the church and at the court. The ecclesiastics who were parted at his command from the lay-sisters whom they kept ostensibly as servants; the thirteen bishops whom he deposed for simony and licentiousness at a single visitation; the idle monks who thronged the avenues to the court, and found themselves the public object of his scorn,—all conspired against the powerful author of their wrongs. Their resentment was inflamed by a powerful party, embracing the magistrates, the ministers, the favourite eunuchs, the ladies of the court, and Eudoxia the empress herself, against whom the preacher thundered daily from the pulpit of St Sophia. A favourable pretext for gratifying their revenge was discovered in the shelter which Chrysostom had given to four Nitrian monks, known as the tall brothers, who, on being excommunicated by their bishop, had fled to Constantinople; and a ready tool was found in Theophilus, bishop of the rival city of Alexandria, who had driven them from their dioceses, and had long circulated in the East the charge of Origenism against Chrysostom. By his instrumentality a synod was called to try or rather condemn the archbishop; but fearing the violence of the mob in the metropolis, who idolized him for the fearlessness with which he exposed the vices of their superiors, it held its sessions in the suburbs of Chalcedon, named the *Oak*, where Rufinus had erected a stately church aud monastery. A bishop and a deacon were sent to accuse the archbishop, and presented to him a list of charges, in which pride, inhospitality, and Origenism were brought forward to procure the votes of those who hated him for his austerity, or were prejudiced against him as a suspected heretic. Four successive summonses were signified to Chrysostom, but he indignantly refused to appear until four of his notorious enemies were removed from the council. Without entering into any examination of the charges brought before them, the synod condemned him on the ground of contumacy; and, hinting that his audacity merited the punishment of treason, called on the emperor to ratify and enforce their decision. He was immediately arrested and hurried to Nicæa in Bithynia. As soon as the news of his banishment spread through the city, the astonishment of the people was quickly exchanged for a spirit of irresistible fury. In crowds they besieged the palace, and had already begun to take vengeance on the foreign monks and sailors who had come from Chalcedon to the metropolis, when, at the entreaty of Eudoxia, the emperor consented to his recal. His return was graced with all the pomp of a triumphal entry, but in two months after he was again in exile. His fiery zeal could not blind him to the vices of the court; and heedless of personal danger he thundered against the profane honours that were addressed almost within the precincts of St Sophia to the statue of the empress. The haughty spirit of Eudoxia was inflamed by the report of a discourse commencing with the words,—"Herodias is again furious; Herodias again dances; she once more demands the head of John;" and though the report was false, it sealed the doom of the archbishop. A new council was summoned, more numerous and more subservient to the wishes of Theophilus; and troops of barbarians were quartered in the city to overawe the people. Without examining it, the council confirmed the former sentence, and condemned him afresh for having resumed his functions without their permission. He was hurried away to the desolate town of Cucusus, among the ridges of Mount Taurus, with a secret hope, perhaps, that he might be a victim to the Isaurians on the march, or to the more implacable fury of the monks. He arrived at his destination in safety; and the sympathies of the people, which had roused them to fire the cathedral and senate-house on the day of his exile, followed him to his obscure retreat. His influence, however, became more powerfully felt in the metropolis than before. In his solitude he had ample leisure for forming schemes of missionary enterprise; and by his correspondence with the different churches, he at once baffled his enemies, and gave greater energy to his friends. This roused the emperor to visit him with a severer punishment. An order was despatched for his instant removal to the extreme desert of Pityus; and his guards so faithfully obeyed their cruel instructions that, before he reached the sea-coast of the Euxine, he expired at Comana in Pontus, in the sixtieth year of his age. His exile gave rise to a schism in the church, and the Johannists (as they were called) did not return to communion with the archbishop of Constantinople till the relics of the saint were, 30 years after, brought back to the Eastern metropolis with great pomp, and the emperor publicly implored forgiveness from Heaven for the guilt of his ancestors. The festival of St Chrysostom is kept in the Greek Church, Nov. 13, and in the Latin Church, Jan. 27.

His works are exceedingly voluminous, and consist chiefly of homilies, commentaries, smaller treatises, epistles, and liturgies. Their excellence is powerfully shown in the history of the times, for the illustration of which they afford highly valuable materials. The best edition is that of Bernard de Montfaucon in 13 vols. fol., 1718-1738; but numerous MSS.

still remain unedited. Some of his homilies and commentaries are translated in the *Library of the Fathers*, published at Oxford. As authorities for the facts of his life, the most valuable are the ecclesiastical histories of Socrates, Sozomen, and Theodoret; and amongst the moderns Erasmus, Cave, Lardner, and Tillemont, with the more recent church history of Neander, and his monogram on the Life and Times of Chrysostom, translated by J. C. Stapleton.

CHUB, a river fish, of the genus Cyprinus. See index to ICHTHYOLOGY; and ANGLING, vol. iii. p. 161.

CHUBB, THOMAS, (1679-1747,) a noted deist, was born at East Harnham, near Salisbury, where he was apprenticed to a glover, and afterwards became a tallow chandler. His parents were poor, and unable to afford him a liberal education; but, in the midst of his other avocations, he contrived to make considerable progress in scientific study. His favourite subject, however, was theology; and from discussing the question in a debating society which he himself had instituted, he soon became publicly engaged in the trinitarian controversy, then warmly agitated between Clarke and Waterland. He embodied his opinions in a dissertation, which was afterwards published under the title of *The Supremacy of the Father asserted.* Besides this, he published a quarto volume of tracts, and some minor practical and controversial works.

CHUDLEIGH, a market-town of England, county of Devon, and hundred of Exminster, near the Teign, 9 miles S.S.W. of Exeter, and 182 miles from London. Pop. (1851) 2401. The town is pleasantly situated on an acclivity, and consists chiefly of a single street. It has a church, 2 chapels, and a grammar-school with 3 exhibitions to Cambridge. Market-day Saturday. The greater part of the town was destroyed by fire in 1808. The district is famous for its cider. In the vicinity are Ugbrook Park the seat of Lord Clifford, and Chudleigh rock, a great mass of limestone, with a remarkable cavern.

CHUMBUL, a river of Hindustan, which rises in the centre of the province of Malwah, within 15 miles of the Nerbuddah. From thence its course is due N., until it passes the city of Kotah; after which, being augmented by many smaller streams, it turns more to the E., and falls into the Jumna 20 miles from Etaweh, in Lat. 26. 30., Long. 79. 19. The course of this river is computed at 570 miles, described in a form nearly semicircular; and the breadth of its channel at the ford of Kyteree, near Dhoolpoor, is three-quarters of a mile. This river is supposed by Major Rennell to be the Sambus of Arrian. It is now the boundary between the Rajpoot territories and those of Sindia to the south.

CHUMPANEER, in Hindustan, a hill fort situated on an isolated rock rising 2500 feet above the plains of Gujerat, one of the most level provinces of Hindustan. To the northward of the mountain are the remains of an ancient city, the ruins of which extend several miles on each side, and are at present covered with an impenetrable jungle, the abode of tigers and Bheels, a fierce race of predatory mountaineers. The town is inclosed by a stone wall of good workmanship, within a small space of an oblong figure, which is three-fourths of a mile long, and three furlongs broad. The mountain is strengthened by two forts; the upper deemed impregnable by the natives, and containing a Hindu temple; while the defences of the lower part are extensive, and the whole of difficult approach. In 1812 the town of Chumpaneer contained four hundred houses, of which about only one-half were inhabited, principally by emigrants from other parts of Gujerat. It is supposed to have been the capital of an ancient principality long before the Mohammedan conquest; and it was taken about the end of the fifteenth century, by Mahmoud VII. of Guzerat, after a siege or blockade of twelve years. In 1534, it was taken by the Mogul emperor Humayon. In 1582, it is described as a place of considerable strength, surrounded by extensive ruins, Hindu as well as Mohammedan. On the dismemberment of the empire of Delhi, in the latter part of the eighteenth century, it was seized by the Mahrattas, who always considered it as a strong place, and had a good garrison in it. It was taken from Sindia by the British in 1802, but was restored to him in the following year. It is 55 miles E. by N. from Cambay. Long. 73. 30. E., Lat. 22. 31. N.

CHUNAM, a kind of calcareous cement or stucco used in India to cover houses. It contains various ingredients.

CHUNAR or CHUNARGHUR, a town and fortress of Hindustan, in the British district of Mirzapore fort, situated on the south bank of the Ganges. The fort is built on the top of a solid rock, which rises abruptly from the plain, and projects into the river. It is inclosed all around by a stone wall and small towers, and is a place of great strength; but its chief defence against escalade is a number of large round stones, which are piled round the rampart, ready to be hurled down on any rash assailant. It has a small citadel, and extensive magazines. This fortress has been sometimes used as a state prison; but the rays of the sun reflected from the rock render it very hot and unhealthy. The town of Chunar consists of a straggling collection of native huts and European dwellings. Its population has been returned at 11,058. There is here an English church which belongs to the Church Missionary Society, built in good style, and embellished with a Gothic steeple. The batteries completely command the navigation of the river, so that no vessel can pass without inspection. Chunarghur is a very ancient fortress, and there is no record of its original foundation. The first time it is mentioned in Mohammedan history is in the year 1491, when it was in possession of Sing Joanpore. When garrisoned by Baber in 1529, it appears to have been a place of importance, though its vicinity was infested by the elephant, tiger, and rhinoceros. In 1530 it was the residence of Shere Khan, the Afghan who expelled Humayon the son of Baber from Hindustan. In 1575 it was recovered by the emperor Akbar, after a siege of six months. In 1763 it was seized by the nabob of Oude; and it was then attacked by the English, under general Carnac, who were repulsed by the garrison rolling down large stones on the storming party; but the rampart being breached in the S.W. quarter, the garrison surrendered. Five years later, it was formally surrendered by treaty to the East India Company. The hills, which approach very near the town, contain quarries of excellent freestone, which is in great demand at Benares and other towns down the river. Distance from Calcutta, N.W. 437 miles. N. Lat. 25. 5. E. Long. 83.

CHUPMESSAHITES, a sect of Mohammedans who believe that Jesus Christ is God, the true Messiah and Redeemer of the world, but render him no public or declared worship.

CHUPRAH, a large town of Hindustan, in the province of Bahar, and chief town of the district of Sarun, situated on the north bank of the Ganges. It was first entered in 1757 by the British, in pursuit of a French detachment under Mr Law, which had entered into the service of the nabob of Oude. Though the town has but one street passable for wheeled vehicles, it is said to contain a large number of handsome native houses. The place is well situated for commerce, enjoying intercourse by means of the river with all the towns between it and Calcutta. It is 32 miles W.N.W. from Patna. Long. 84. 46. E. Lat. 25. 46. N.

CHUQUISACA, the capital city of Bolivia, in the department of Chuquisaca, is situated on a plain, surrounded by a chain of eminences which shelter it from the winds, at an elevation of 9331 feet above the level of the sea. The climate is mild and healthy, the temperature throughout the year presenting no great variation; but in winter heavy storms are not unfrequent, and the rains continue a con-

siderable time. The vegetation of the surrounding district is rich and luxuriant, and accordingly it is looked upon as one of the gardens of Bolivia which supply the necessaries of life to those inhabiting higher and less prolific regions. Chuquisaca formerly was named La Plata from its contiguity to silver mines. It was founded in 1539 by one of Pizarro's captains. In 1551 it was erected into a bishopric, and in 1608 was raised to an archbishopric. The best houses are only one story high; but they are roomy, and in general have gardens planted with European fruit-trees. The public buildings of this city include a university, a large and handsome cathedral, a parochial church, five monastic establishments; and besides these there are several splendid churches, a conventual hospital, and three nunneries. Pop. about 25,000. See Bolivia.

CHUR, French Coire, the capital of the Swiss canton of Grisons, situated in a valley traversed by the Plessur, an affluent of the Rhine, which it joins about one mile below the town. Pop. (1851) 6183. It is a walled town with narrow and crooked streets, but it possesses a considerable transit trade, being situated on the high road over the Splügen and Bernardin passes, by which the manufactures of St Gall, Glarus, and Zürich are transported to Italy. About one-third of its inhabitants are engaged in that traffic. It is the seat of a bishop, and has, besides a cathedral, 2 churches, 2 convents, an episcopal palace, town hall, and public library. Manufactures, zinc-plates and cutlery.

CHURCH (κύριος a lord, hence τὸ κυριακόν, *the Lord's house*—whence also *kyrke*) has several significations, according to the different subjects to which it is applied.

First, it denotes the collective body of Christians, or all those who acknowledge Christ as the Saviour of mankind; and hence denominated by ancient writers the Catholic or Universal Church. Sometimes the word is used in a sense still more extensive, including the Church Militant, or the assembly of the faithful on earth; the Church Triumphant, which is that of the faithful already in glory; to which the Catholics add the Church Patient, or that of the faithful in purgatory.

Church is also applied to a particular congregation of Christians who associate together and participate in the institutions of Christ, with their proper pastors and ministers. In this sense we read of the church of Antioch, the church of Alexandria, the church of Thessalonica, &c.

Church likewise denotes a particular sect of Christians, distinguished by particular doctrines and ceremonies; as the Roman Catholic Church, the Greek Church, the Reformed Church, the Church of England, the Church of Scotland.

The Latin or Western Church comprehends all the churches of Italy, France, Spain, Africa, the north, and all other countries whither the Romans carried their language. Great Britain, part of the Netherlands, part of Germany, and part of the north, have been separated from this church ever since the time of the Reformation, and constitute the Reformed Church, or what the Roman Catholics denominate the Western Schism.

The Greek or Eastern Church comprehends the churches of all the countries anciently subject to the Greek or Eastern empire, and through which their language was carried; that is, all the space extending from Greece to Mesopotamia and Persia, and thence into Egypt. This church has been divided from the Latin Church ever since the time of the emperor Phocas.

The Gallican Church denotes the Church of France under the government and direction of their respective bishops and pastors. This church has always enjoyed certain franchises and immunities, not as grants from popes, but as derived from her origin or foundation, and which she has taken care to maintain. These liberties depend upon two maxims; the first of which is, that the pope has no authority or right to command or order anything, either in general or in particular, in which the temporalities and civil rights of the kingdom are concerned; and the second, that notwithstanding the pope's supremacy is acknowledged in cases purely spiritual, yet in France his power is limited and regulated by the decrees and canons of certain ancient councils received in that realm.

Church is also used to signify the body of ecclesiastics, or the clergy, in contradistinction to the laity.

Church is used for the place where a particular congregation or society of Christians assemble for the celebration of divine service. In this sense churches are variously denominated, according to their rank, degree, discipline, and the like; as the metropolitan church, the patriarchal church, cathedral church, parochial church, collegiate church, &c.

In ecclesiastical writers we meet with Grand Church, used to signify the chief church of a place. Thus, in the Greek liturgy, the church of St Sophia at Constantinople, the see of the patriarch, founded by Constantine, and consecrated under Justinian, is denominated the Grand Church.

The first church publicly built by the Christians is supposed by some to have been that of St Saviour at Rome, founded by Constantine; while others contend that several churches abroad, called by the name of St Peter Vivus, were built in honour of that apostle during his lifetime.

High Church was a denomination originally given to those otherwise called Nonjurors, who refused to acknowledge the title of William III. Prince of Orange to the crown of Great Britain, on the plea that James II., though excluded, was still their rightful sovereign. This appellation was given them because they entertained high notions of the dignity and power of the church, and the extent of its prerogatives and jurisdiction. And those, on the contrary, who disapproved of the succession and obstinacy of the Nonjurors, were called Low Churchmen, as being distinguished by their moderation towards dissenters, and less ardent in extending the limits of church authority. The denomination of High Churchmen is now more generally applied to all who form lofty and ambitious conceptions of the authority and jurisdiction of the church, and who would raise it to an absolute independence of all civil power.

Church-Wardens (*ecclesiæ guardiani*) in the English ecclesiastical polity, are the guardians or keepers of the church, and the representatives of the parish. Churchwardens are appointed by the minister, or by the parish, and sometimes by both together, to superintend the church, its property and concerns, and the behaviour of the parishioners.

CHURCHILL, John, Duke of Marlborough, was born at Ashe in Devonshire, June 24, 1650. He was second son of Sir Winston Churchill, a stanch royalist, who for his services during the civil war was rewarded with considerable preferment at court. Thither young Churchill followed his father before he had acquired even a common education; but this deficiency proved no barrier in the way of an intimacy which soon sprung up between him and the Duke of York, afterwards James II. In 1666 he was made an ensign of the guards during the first Dutch war; and afterwards served at Tangier in the war against the Moors. In 1672 Churchill joined the Duke of Monmouth, who commanded a body of auxiliaries in the French service, and soon afterwards he was made captain in the duke's own regiment. At the siege of Nimeguen, which happened during that campaign, he distinguished himself so much that he gained the admiration of Marshal Turenne, who bestowed on him the name of "the handsome Englishman." In 1673 he was present at the siege of Maestricht, and afterwards received a public acknowledgment from the king of France for his services on that occasion. The Duke of Monmouth too, who had the direction of the attack, acknowledged to Charles II. that he owed his life to Churchill's bravery. In 1681 he married Sarah, daughter of Richard Jennings,

Esq. of Sandrich, Hertfordshire, a lady who like himself had spent her early life at court, and whose genius and temper exercised a very remarkable influence on his character and fortunes. Soon after this, through the patronage of the Duke of York, he obtained the baronetcy of Eyemouth, and a colonelcy in the third troop of guards. On the accession of King James he was created Baron Churchill of Sandrich, in the county of Hertford, and made brigadier-general of his Majesty's army in the west; where, when the Duke of Monmouth attempted to surprise the king's army while the Earl of Feversham and the greater part of the officers were in bed, he kept the enemy in play till the king's forces had time to form, and thereby saved the whole army. At the time of the revolution he hesitated for a while between the two contending parties, offering his services to the one, while he accepted command under the other; but at length he joined the Prince of Orange. He was graciously received in the prince's camp; and for his services in augmenting and remodelling the army was invested with the rank and title of lieutenant-general. In 1689 he was sworn a member of the privy-council, and one of the gentlemen of the king's bed-chamber; and immediately after he was raised to the dignity of Earl of Marlborough, in the county of Wilts. He assisted at the coronation of their majesties; and was soon afterwards appointed commander-in-chief of the English forces sent over to Holland, where he first laid the foundation of that fame which was afterwards spread over all Europe. In 1690 he was appointed general of the forces sent to Ireland, and captured the garrisons of Cork and Kinsale. In the following year he was sent by King William to Flanders on a preparatory expedition, for the purpose of organizing the army before the arrival of the king. In 1692 he was dismissed from all his employments, and not long afterwards committed to the Tower, on an accusation of high treason. This aspersion on his character seems to have been without foundation. Marlborough was soon restored to favour, and, in 1698, appointed governor to the Earl of Gloucester; upon which occasion King William paid him this extraordinary compliment:—"My lord, make him but what you are, and my nephew will be all I wish to see him." The same day he was again sworn of the privy-council; and in July following he was declared one of the lords justices of England, for the administration of the government, an office with which he was three times successively invested in the king's absence. In 1701 he was appointed general of infantry, commander-in-chief of the English forces, and ambassador extraordinary and plenipotentiary at the Hague. Upon the accession of Queen Anne to the throne, he was elected into the order of the garter, declared captain-general of all her Majesty's forces, and sent as ambassador extraordinary and plenipotentiary to Holland. His warlike exploits, and the vicissitudes of his political career have been sufficiently detailed under BRITAIN; we shall therefore only mention here the rewards and honours conferred upon him for these brilliant achievements. After his first campaign he was created Marquis of Blandford and Duke of Marlborough, with a pension of L.5000 out of the post-office, to devolve for ever upon those enjoying the title of Duke of Marlborough. In 1703 he met Charles III., afterwards emperor, proceeding to Spain, by whom he was presented with a sword set with diamonds. In 1704, having forced the enemy's lines at Schellenberg, he was honoured with a letter of thanks from the emperor Leopold, written with his own hand. After the battle of Blenheim he received congratulatory letters from most of the potentates in Europe, particularly from the states-general, and from the emperor, who desired him to accept of the dignity of a prince of the empire. With permission of his sovereign, accordingly, he was created Prince of Mildenheim, in the province of Suabia. When the campaign was ended, he visited the court of Prussia, where he succeeded in suspending the disputes with the Dutch about King William's estate; and by his address on the occasion gained the acknowledgment from the whole confederacy that the duke had done the greatest service possible to the common cause. Upon his return to England, the queen, to perpetuate his memory, granted the interest of the crown in the honour and manor of Woodstock and hundred of Wotton to him and his heirs for ever. In 1705 he made a tour to Vienna, upon the invitation of the emperor Joseph, who received him in the most gracious manner, and made him a grant of the lordship of Mildenheim. After the campaign of 1708, the speaker of the House of Commons was sent to Brussels on purpose to compliment him; and on his return to England he received a second compliment in the House of Lords. After the change of the ministry in 1710, his interest daily declined; and in the beginning of 1712 he was removed from all his offices. Finding his disgrace sealed (if it was not actually procured) by the estrangement which then existed between the Duchess of Marlborough and the queen, he spent a considerable part of his time abroad—visiting his principality of Mildenheim, and several towns in Germany—and arrived in England only on the day of the queen's death. Receiving a cordial welcome from the nobility and foreign ministers, he attended George I. in his public entry into London; and was appointed captain-general, colonel of the first regiment of foot guards, one of the commissioners for the government of Chelsea hospital, and master-general of the ordnance. These dignities he retained till his death, which took place at Windsor Lodge, June 16, 1722; and though 73 years old and weakened by two previous paralytic strokes, he retained his mental faculties in full vigour to the last. Upon his demise, all parties united in doing honour to his merit; and his corpse was interred, on the 9th of August following, in Westminster Abbey.

One of the most generous testimonies to the abilities and greatness of Marlborough is from the pen of Bolingbroke, who, though one of the keenest of his political opponents, is known to have said to a parasite who ridiculed the avarice of Marlborough—"He was so very great a man, that I had forgotten he had that vice." Speaking in his *Letters on History* of the consternation raised among the allies by the death of King William, and of the joy which that event gave to the French, Bolingbroke observes, that "a short time showed how vain the fears of some and the hopes of others were. By his death the Duke of Marlborough was raised to the head of the army, and indeed of the confederacy; where he, a new, a private man, a subject, acquired, by merit and by management, a more deciding influence than high birth, confirmed authority, and even the crown of Great Britain, had given to King William. Not only all the parts of that vast machine, the Grand Alliance, were kept more compact and entire, but a more rapid and vigorous motion was given to the whole; and instead of languishing out disastrous campaigns, we saw every scene of the war full of action. All those wherein he appeared, and many of those wherein he was not then an actor, but abettor, however, of their action, were crowned with the most triumphant success. I take, with pleasure, this opportunity of doing justice to that great man, whose faults I knew, whose virtues I admired; and whose memory, as the greatest general and as the greatest minister that our country, or perhaps any other, has produced, I honour."

So far as his military ability is concerned, posterity has not hesitated to accept the verdict. Without inventing for himself a new system of strategy, or at all improving the military science of the day, he was never defeated in a battle, and never unsuccessful in a siege. He was the animating spirit of the Grand Alliance; and by his personal address at the foreign courts, as well as his skill in the field, he proved the bulwark of European liberties. His conduct at the era of the revolution, however, has been regarded as a

Churchill. stigma to his character; and to this has been added the charge of deliberate treason in privately communicating to the French intelligence of a secret expedition against Brest. In the words of Mr Macaulay—"His former treason, thoroughly furnished with all that makes infamy exquisite, placed him under the disadvantage which attends every artist from the time that he produces a masterpiece. Yet his second great stroke may excite wonder, even in those who appreciate all the merit of the first. Lest his admirers should be able to say that, at the time of the revolution, he had betrayed his king for any other than selfish motives, he proceeded to betray his country. He sent intelligence to the French court of a secret expedition intended to attack Brest. The consequence was, that the expedition failed, and that 800 British soldiers lost their lives by the abandoned villany of a British general. Yet this man has been canonized by so many eminent writers, that, to speak of him as he deserves, scarcely seems decent."

The following anecdotes may be noticed as somewhat characteristic:—One of the first things which he did, when very young, was to purchase a box to put his money in; an indication of the economical, not to say avaricious, temper which accompanied him through life. Dr Joseph Warton relates, that on the evening of an important battle the duke was heard to chide his servant for having been so extravagant as to light four candles in his tent when Prince Eugene came to confer with him. Richardson the painter has recorded a pleasing instance of the duke's equanimity, for which, indeed, he was always remarkable. "The Duke of Marlborough," says the writer, "riding out once with Commissary Marriot near the commissary's house in the country, it began to rain, and the duke called for his cloak; Marriot having his put on by his servant immediately. The duke's servant not bringing the cloak, he called for it again, but the man was still puzzling about the straps and buckles. At last, as it now rained very hard, the duke called again, and asked him 'what he was about that he did not bring his cloak?' 'You must stay,' grumbled the fellow, 'if it rains cats and dogs, till I can get at it.' The duke only turned to Marriot and said, 'I would not be of that fellow's temper;' reminding us of the saying of Seneca, *Quid est quare ego servi mei hilarius responsum, et contumaciorem vultum, flagellis et compedibus expiem?*"

See *Memoirs and Correspondence of the Duke of Marlborough*, by Archdeacon Coxe, in 3 vols. 4to, and Alison's *Life of Marlborough*, 2 vols. 8vo.

CHURCHILL, *Charles* (1731-1764), a celebrated satirist, was born at Westminster, where his father was curate and lecturer of St John's. He was educated at Westminster school; but made so little progress in his studies that when he went to Oxford he was rejected on account of his deficiency in the classics,—a circumstance which probably explains the frequent invectives which we find in his works against that university. On his return he again applied to his studies in Westminster school; and after studying theology for some time in retirement at Sunderland, he was ordained priest by Sherlock, bishop of London, and obtained a curacy at Cadbury in Somersetshire. It is said that, while in this situation, he endeavoured to augment his income by keeping a cider-cellar, and thus laid the foundation of his dissoluteness in after life; but this story seems to be without foundation, and is denied by the editor of his works. From Cadbury he removed to Wales; and thence, on the death of his father, to Westminster, where he was not unfavourably known for his talents and deportment. In spite, however, of his efforts to improve his income by teaching in a boarding-school, his debts soon outstripped his means, and he was only saved from incarceration by the interposition of Dr Lloyd, a master in Westminster school. His intimacy at this time with Robert Lloyd, a dissolute poetaster, the son of his benefactor, exerted an unhappy influence on his character. The first of Churchill's poems for which he could find a publisher was the *Rosciad*, a rude satire on the theatrical notabilities of the time; but it was not till a second edition was called for that he ventured to affix his name to the work. His next performance was his *Apology to the Critical Reviewers*, which contains a vigorous reply to the attacks made on his former production. While his writings were thus furnishing general amusement, his private life was viewed with unmitigated disgust. He abandoned his wife, resigned his clerical dignities, and openly devoted himself to a life of pleasure. To palliate his convivial excesses, he wrote a poem called *Night*, in which he justified his conduct by pleading that he never disguised it. His next poem, entitled the *Ghost*, is aimed at Dr Johnson, who had expressed an unfavourable opinion of Churchill's previous works, and is satirized under the name of Pomposo. A political squib, entitled *Prophecy of Famine*, was more successful than either of these works. It was written in the spirit of the *North Briton*, and principally to gratify Mr Wilkes, who augured well of its success on the ground that it was at once personal, poetical, and political. His succeeding pieces were carelessly written, and far less successful. *Gotham*, *Independence*, *The Times*, &c., were written rather from a desire to profit by his fame than to advance it. Churchill died of a miliary fever at Boulogne, whither he had gone on a visit to his friend Wilkes. (See *Genuine Memoirs of Mr Churchill*, 12mo, 1765.) His collected poems were published in 2 vols. 8vo, 1779.

Churchyard ‖ Chusan.

CHURCHYARD, a piece of ground adjoining to a church, and set apart for the interment of the dead. In the Church of Rome such grounds are consecrated with great solemnity; and if afterwards profaned, as by the burial of an infidel, a heretic, or an unbaptized or excommunicated person, the ceremony of *reconciliation* is performed with all the solemnity of the original consecration.

CHURCHYARD, *Thomas*, a poet who flourished in the reigns of Henry VIII., Edward VI., Mary, and Elizabeth. He was born at Shrewsbury; and inherited a small patrimony, which was soon exhausted in a fruitless attendance on the court. He found his only recompense in having gained the favour of Lord Surrey, who retained him as a domestic, and encouraged his first poetical attempts. On his patron's death he joined the army; and in the engagements at which he was present he was frequently wounded, and twice made prisoner. He published several pieces, which were afterwards collected into one volume under the title of *Churchyard's Chips*; and also the tragedy of *Thomas Moubray, Duke of Norfolk*. He died in 1604.

CHURN (Saxon *cierne*), a machine for separating the oily parts of milk or cream from the caseous and serous parts, to make butter. (See DAIRY.) The common churn is a vessel in the shape of the frustrum of a cone, in which the milk is agitated by means of a perforated circular board attached to a long rod, which is worked up and down through an orifice in the lid of the vessel; or several such boards are arranged around a horizontal spindle, one end of which is made to pass through the side of the vessel, and attached to a handle. In some churns the agitation of the milk is increased by a double apparatus acting in contrary directions. The construction of churns however varies greatly.

CHUSAN, the principal of an immense group of smaller islands off the eastern coast of China, in Lat. 30. N. Long. 122. E. It lies N.W. and S.E., and has a circumference of $51\frac{1}{4}$ miles—the extreme length being 20, the extreme breadth 10, and the minimum breadth 6 miles. This island is beautifully diversified with hill and dale, and is well cultivated. Of the numerous small streams which run from the mountains and cross the plains to the sea, the most considerable is the Tungkeang, which falls into the harbour of Tinghae. On most of the hills there is a moderate coating

of earth, which by industry has been rendered very productive. Nineteen-twentieths of the inhabitants are engaged in agriculture. Wherever it is possible to rear rice, the cultivation of every other product is abandoned; yet the quantity produced is not sufficient for the wants of the inhabitants. Millet, wheat, sweet potatoes, yams, taros, &c., are also grown. The tea plant is found almost everywhere, but is treated with little or no care. Chusan annually exports about 30,000 dols. worth. The cotton plant is largely cultivated near the sea. The capital, Tinghae, stands about half a mile from the beach, and is surrounded by a wall nearly 3 miles in circuit. The ditch outside the wall is interrupted on the N.W. side by a spur from a neighbouring hill, which projects into the town, and forms an easy access to an attacking force on that side The town is traversed by canals, and the harbour, which has from 4 to 8 fathoms water, is landlocked by several islands. Temple or Joss-house Hill, which commands the town and harbour, is 122 feet high close to the beach, and on its east side there is a canal. The population of the town and suburbs of Tinghae, which at the commencement of 1843 was about 27,500, had increased in 1846 to above 35,000. The population of the entire island was estimated at 200,000. Chusan has but few manufactures; of these the chief are coarse cotton stuffs and agricultural implements. There are salt works on the coast; and the fisheries employ a number of the inhabitants. In Tinghae a considerable business is carried on in carving and varnishing. The principal exports are fish, coarse black tea, cotton, vegetable tallow, sweet potatoes, and some wheat. Chusan was taken by the British forces in 1840 and 1841, and retained till 1846 as a guarantee for the fulfilment of the stipulations of the treaty.

CHUTTERPOOR, a city of Hindustan, in the province of Bundelcund. It is a very ancient town, having been established by rajah Chuttersal, the founder of the short-lived independence of Bundelcund, who occasionally made it his residence. It was in consequence a very flourishing city, and an important commercial mart, being a great entrepôt of trade between Benares and the Deccan, and at a very short distance from the diamond mines of Pannah. The town is still a thriving place, but maintains its prosperity less by its transit trade than by its manufactures. The principal articles of fabrication are paper and coarse cutlery. The territory, of which this town is the chief place, contains an area of 1240 square miles, with a population of 120,000. The revenue is stated at L.30,000 per annum; and a military force of 100 cavalry and 1000 infantry is maintained by the chief. As Pertaub Singh, the present rajah, has no male issue, the territory, upon his decease, would have lapsed to the paramount power: in acknowledgment, however, of the fidelity of the present rajah and his predecessor, and of the beneficial administration of Pertaub Singh, the British government has recognized a successor to the present rajah in the person of his grand-nephew Juggut Singh, whom Pertaub wishes to adopt. Distance from Agra 180 miles; from Calcutta 600. Lat. 24. 55.; Long. 79. 39.

CHYLE (χυλός, *juice*), the nutritious fluid separated from the chyme in the process of digestion. See Anatomy, vol. ii. p. 782.

CHYTLA, in *Grecian Antiquity*, a mixture of water and oil, used in libations to the dead; and also to rub into the skin after bathing.

CIBBER, Colley, a dramatic writer, and poet-laureate to George II., was the son of Caius Gabriel Cibber, a distinguished German sculptor, and was born in London in 1671. At the age of eleven he was sent to the free school of Grantham in Lincolnshire, where he was educated, and whence he returned to London in 1687. In the following year he joined the army of the Prince of Orange as a volunteer; but in 1689 he left the service and betook himself to the stage, where at first he met with very indifferent success, acting originally for a salary of ten and afterwards of fifteen shillings a-week. In course of time he gradually rose in his profession, till in 1711 he became joint patentee in the management of Drury Lane, and distinguished himself especially by his impersonations of old men and fops. On the death of Eusden the poet-laureate in 1730, Cibber was appointed to succeed him in that office. On this occasion he retired from the stage; to which however he was tempted to return from time to time by an offer of fifty guineas a night. In 1757, shortly after he had completed his 86th year, he was found dead in his bed on the morning of December 12th. Cibber's principal comedies are entitled "Love's last Shift," "Love makes a Man," "She would and She would not," "The Nonjuror" (founded on the Tartuffe of Molière), and "The Careless Husband," which in spirit and finish is superior to all the others. His "Apology" for his life is interesting and humorous, and throws much light on contemporary social history. It has often been reprinted.

CIBORIUM, in *Antiquity*, a drinking-cup, so called from the κιβώριον or seed-vessel of the Egyptian bean, which in Egypt was applied to that use. (Hor., *Od.* ii. 7.)

Ciborium also denotes a kind of architectural structure composed of an arched vault or dome, carried or supported on four columns. In Roman Catholic countries these are erected over shrines and altars. The word is likewise applied less properly to the pyx or box in which the host is preserved.

CICACOLE, a town of Hindustan, British province of Ganjam, presidency of Madras, with a military cantonment, on the north bank of the river Naglandee. Pop. about 50,000. The district of which it is the chief place formerly constituted one of the five Northern Circars, designated the Circar of Cicacole; but the tract is now comprised within the province of Ganjam. Distance of town from Vizagapatam, N.E. 58 miles; from Madras, N.E. 435. Lat. 18. 18.; Long. 83. 58.

CICATRIX (*Latin*), the scar left by a wound or ulcer when healed.

CICERO, Marcus Tullius, the celebrated Roman orator, was born in the year of Rome 647, or about 105 years before Christ. His father Marcus Tullius, who was of the equestrian order, took great care of his education, which was directed particularly with a view to the bar. On his first appearance in public, young Tully declaimed with such vehemence against Sylla's party, that it became expedient for him to retire into Greece, where he attended the Athenian orators and philosophers, and greatly improved both in eloquence and knowledge. Here he met with his school-fellow Titus Pomponius, who, from his love of Athens, and having spent a great part of his days in that city, obtained the surname of *Atticus;* and here they revived and confirmed that noted friendship which subsisted between them through life with unshaken constancy and affection. From Athens Tully passed into Asia, and after an excursion of two years returned to Italy much improved by his travels.

Cicero had now established himself at Rome, where, after one year more spent at the bar, he obtained the dignity of questor. Among the causes which he pleaded before his questorship, was that of the famous comedian Roscius, whom singular excellence in his art had recommended to the familiarity and friendship of the greatest men in Rome. The questors were the general receivers or treasurers of the republic, and were sent annually into the provinces assigned them by lot. The island of Sicily happened to fall to Cicero's share, including that part of it,—for it was considerable enough to be divided into two provinces,—which was called Lilybæum. The office of questor he received, not as a gift, but as a trust; and he acquitted him-

self so well in discharge of it, that he gained the love and admiration of all the Sicilians. Before he left Sicily, he made the tour of the island, in order to visit every thing curious, especially the city of Syracuse, at which place he pointed out the tomb of Archimedes to the magistrates, who were showing him the curiosities of the place; but, to his surprise, he found that they knew nothing either of the tomb or of him whose ashes it contained.

We have no account of the precise time of Cicero's marriage with Terentia; but it is supposed to have been celebrated immediately after his return from his travels to Italy, when he was about thirty. Being now disengaged from his questorship in Sicily, by which first step in the legal gradation and ascent of public honours he had gained an immediate right to the senate, and an actual admission into it during life, he again settled in Rome, where he employed himself constantly in defending the persons and properties of its citizens, and indeed became a general patron of causes. Five years had scarcely elapsed since Cicero's election to the questorship (this being the proper interval prescribed by law before he could hold the next office), when he was, in his thirty-seventh year, elected ædile by the unanimous suffrages of the tribes, and in preference to all his competitors. After Cicero's election to the ædileship, but before his entrance upon office, he undertook the famous prosecution of Verres, the late prætor of Sicily, who was charged with many flagrant acts of injustice, rapine, and cruelty, during his triennial government of that island. This was one of the most memorable transactions of his life, one for which he was greatly and justly celebrated by antiquity, and for which he will, in all ages, be admired and esteemed by the friends of mankind. The result was, that, by his diligence and address, he so confounded Hortensius, though the reigning orator at the bar, and usually styled the king of the forum, that his majesty had nothing to say for his client. Verres, despairing of all defence, submitted immediately, without waiting the sentence, to a voluntary exile, in which condition he lived many years, forgotten and deserted by all his friends. He is said to have been relieved in this miserable situation by the generosity of Cicero; but at length he was proscribed and murdered by Mark Antony, for the sake of those fine statues and Corinthian vessels of which he had plundered the Sicilians.

After the usual interval of two years from the time of his being chosen ædile, Cicero offered himself as a candidate for the prætorship; and, in three different assemblies convened for the choice of prætors, two of which were dissolved without effect, he was every time declared the first prætor by the suffrages of the centuries. He was now in the full career of his fortunes, and in sight, as it were, of the consulship, the grand object of his ambition; and therefore, when his prætorship terminated, he refused to accept any foreign province, the usual reward of that magistracy, and the chief fruit which the generality proposed from it. He had no particular love for money, and no genius for war; so that those governments had no charms for him. The glory which he pursued was to shine in the eyes of the city as the guardian of its laws; to teach the magistrates how to execute, and the citizens how to obey them.

Being now in his forty-third year, the proper age required by law, he declared himself a candidate for the consulship, along with six competitors, L. Sulpicius Galba, L. Sergius Catilina, C. Antonius, L. Cassius Longinus, Q. Cornificius, and C. Licinius Sacerdos. The first two were patricians; the next two plebeians, yet noble; the last two the sons of fathers who had first imported the public honours into their families; Cicero was the only *new man*, as he was called, among them, or person of the equestrian rank. These were the competitors; and in the competition the practice of bribing was carried on openly and shamefully by Antony and Catiline. However, as the election approached, Cicero's interest appeared to be superior to that of all the candidates; for the nobles themselves, though always envious of and desirous to depress him, yet, considering the dangers which threatened the city from many quarters and seemed ready to burst out into a flame, they began to think him the only man qualified to preserve the republic, and to quash the cabals of the desperate, by the vigour and prudence of his administration. The method of choosing consuls was not by an open vote, but by a kind of ballot, or little tickets of wood distributed to the citizens, with the names of the several candidates inscribed upon each. But in Cicero's case the people were not content with this secret and silent way. Before they came to any scrutiny, they loudly and universally proclaimed Cicero the first consul; so that, as he himself says, "he was not chosen by the votes of particular citizens, but by the common suffrage of the city; not declared by the voice of the crier, but by that of the whole Roman people."

Cicero had no sooner entered upon his office than he had occasion to exert himself against P. Servilius Rullus, one of the new tribunes, who had been alarming the senate with the promulgation of an agrarian law; the purpose of which was to create a decemvirate, or ten commissioners, with absolute power for five years over all the revenues of the republic, to distribute them at pleasure to the citizens, and to exercise other functions equally incompatible with the existence of society. These laws used to be greedily received by the populace, and were therefore proposed by factious magistrates as often as they had any point to carry with the multitude against the public good; so that Cicero's first business was to quiet the apprehensions of the city, and to baffle, if possible, the intrigues of the tribune. Accordingly, in an artful and elegant speech from the rostra, he gave such a turn to the inclination of the people, that they rejected this law with as much eagerness as they had ever received one. But the affair which constituted the great glory of his consulship, and which has transmitted his name with such lustre to posterity, was the skill he showed, and the unwearied pains he took, in suppressing the conspiracy which had been formed by Catiline and his accomplices for the subversion of the commonwealth. For this great service he was honoured with the glorious title of *Pater Patriæ*, or Father of his Country, a title which he retained for a long time afterwards.

Cicero's administration was now at an end; but he had no sooner quitted his office than he began to feel the effects of that envy which is the certain fruit of illustrious merit. He was now, therefore, the common mark, not only of all the factious, against whom he had declared perpetual war, but of another party not less dangerous, the envious, whose united malice never left him from this moment till they had driven him out of the very city which he had so lately preserved. Cicero, upon the expiration of his consulship, took care to send a particular account of his whole administration to Pompey, then occupied with the Mithridatic war in Asia; in hopes no doubt of preventing any wrong impressions there from the calumnies of his enemies, and of drawing from that commander some public declaration in favour of what had been done. But Pompey being informed by Metellus and Cæsar of the ill humour which was rising up against Cicero in Rome, answered him with great coldness, and instead of paying him any compliment, took no notice at all of what had passed in the affair of Catiline; an omission in regard to which Cicero expostulates with him in a letter which is still extant.

About this time Cicero bought a house of Marcus Cras-

sus, on the Palatine Hill, adjoining to that in which he had always lived with his father, and which he is supposed to have given up to his brother Quintius. The house cost him a very large sum, and seems to have been one of the noblest in Rome. The purchase of so expensive a house led to some censure of his vanity, especially as it was effected with borrowed money; a circumstance which he himself does not dissemble, but observes jocosely, with reference to it, that "he was now plunged so deeply in debt, as to be ready for a plot, only that the conspirators would not trust him."

The most remarkable event that happened in this year, which was the forty-fifth of Cicero's life, was the pollution of the mysteries of the Bona Dea by Publius Clodius, a crime which, by an unhappy train of consequences, involved Cicero in a great and unexpected calamity. Clodius had an intrigue with Cæsar's wife Pompeia, who, according to annual custom, was now celebrating in her house those awful sacrifices of the goddess, to which no male creature was ever admitted, and where everything masculine was so scrupulously excluded, that even pictures of that sort were covered during the ceremony. It flattered Clodius's imagination greatly to gain access to his mistress in the midst of her holy ministry; and with this view he dressed himself in a woman's habit, that by the benefit of his smooth face, and the introduction of one of the female servants, he might pass without discovery; but by some mistake between him and his guide, he lost his way when he came within the house, and fell unluckily among the other female servants. Here he was detected by his voice, and the servants alarmed the whole company by their shrieks, to the great amazement of the matrons, who threw a veil over their sacred mysteries, while Clodius found means to escape. The story was presently spread abroad, and raised a general scandal and horror throughout the city. The whole defence which Clodius made when, by order of the senate, he was brought to trial, was to prove himself absent at the time when the offence was committed; for which purpose he produced two men to swear that he was then at Interamna, distant about two or three days' journey from the city. But Cicero being called upon to give his testimony, deposed that Clodius had been with him that very morning at his house in Rome. Irritated by this, Clodius formed a scheme of revenge. This was to get himself chosen tribune, and in that office to drive Cicero out of the city, by the publication of a law, which, by some stratagem or other, he hoped to obtrude upon the people. But as all patricians were incapable of the tribunate by its original institution, so his first step was to make himself a plebeian, by the pretence of an adoption into a plebeian house, which could not yet be done without the suffrage of the people. The first triumvirate had now been formed, being in reality nothing else but a traitorous conspiracy of three of the most powerful citizens of Rome, to extort from their country by violence what they could not obtain by law. Pompey's chief motive was to get his acts confirmed by Cæsar in his consulship, which was now approaching; Cæsar, by giving way to Pompey's glory, thought to advance his own; while Crassus hoped to gain that ascendency by the authority of Pompey and Cæsar which he could not sustain alone. Cicero might have made what terms he pleased with the triumvirate, and even been admitted a partner of their power, or a fourth in their league; but he would not enter into any engagements with the three, whose union he and all friends of the republic abhorred. Clodius, in the mean time, had been pushing on the business of his adoption, which at last he effected, and began soon afterwards to threaten Cicero with all the terrors of his tribunate, to which he was now advanced without any opposition. Both Cæsar and Pompey secretly favoured his scheme; not that they intended to ruin Cicero, but only to keep him under the lash; and if they could not draw him into their measures, or induce him at least to remain quiet, to let Clodius loose upon him. Cæsar, in particular, wanted to distress him so far as to force him to a dependence on himself; and hence, while he was privately encouraging Clodius to pursue him, he was proposing expedients to Cicero for his security. But though his fortunes seemed now to be in a tottering condition, and his enemies daily gained ground upon him, yet he was unwilling to owe an obligation for his safety to any man, far less to Cæsar, whose designs he had always suspected, and whose schemes he never approved. This stiffness in Cicero so exasperated Cæsar, that he resolved immediately to assist Clodius with his whole power to oppress him; while Pompey was all the while giving him the strongest assurances that there was no danger, and that he would sooner be killed himself than suffer him to be hurt.

Clodius, in the mean time, was obliging the people with several new laws, contrived chiefly for their advantage; in the hope, no doubt, that he might thereby introduce with a better grace the ground-plot of the plan for the banishment of Cicero. In short, having caused a law to be enacted, importing, that whoever had condemned a Roman citizen unheard should be banished, he soon afterwards impeached Cicero upon the enactment. It was in vain that the great orator went up and down the city soliciting his cause in the habit of a suppliant, and attended by many of the first young noblemen whom he had taught the rules of eloquence; those powers of speaking which had so often been successful in defending the cause of others, seemed totally to forsake him in pleading his own. He was banished by the votes of the people four hundred miles from Italy; his houses were ordered to be demolished, and his goods set up to sale. It cannot be denied that, in this great calamity, he did not behave himself with that firmness which might have reasonably been expected in one who had borne so glorious a part in the republic, conscious of his integrity, and suffering in the cause of his country; and his letters are for the most part filled with such lamentable expressions of grief and despair, that his friends, and even his wife, were forced sometimes to admonish him to rouse his courage, and to remember his former character. Atticus was constantly putting him in mind of this, and sent him notice of a report which had been brought to Rome by one of Cassius's freed-men, that his affliction had disordered his senses. He was now indeed attacked in his weakest part, the only place in which he was vulnerable. To have been as great in affliction as he was in prosperity, would have been to exhibit a perfection not given to man; yet his very weakness flowed from a source which rendered him the more amiable in all the other relations of his life; and the same tenderness of disposition which made him love his friends, his children, and his country, more passionately than other men, caused him to feel the loss of them more sensibly. When he had been gone a little more than two months, a motion was made in the senate by one of the tribunes, who was his friend, to recal him, and repeal the laws of Clodius, to which the whole house readily agreed. Many obstructions, as may be easily imagined, were given to it by the Clodian faction; but this made the senate only more resolute to effect the object proposed. They passed a vote, therefore, that no other business should be done till Cicero's return had been carried; which it at last was, and in so splendid and triumphant a manner, that he had reason, he says, to fear lest people should imagine that he himself had contrived his late flight for the sake of so glorious a restoration.

Cicero, now in his fiftieth year, was restored to his former dignity, and soon afterwards to his former fortunes,

satisfaction being made to him for the ruin of his estates and houses, which last were rebuilt by himself with more magnificence than before. But about this time he had domestic grievances which touched him very nearly, and which, as he signifies obscurely to Atticus, were of too delicate a nature to be expressed in a letter. They arose chiefly from the petulant humour of his wife, which began to give him frequent occasions of chagrin; and, by a series of repeated provocations, confirmed in him the settled disgust which at last ended in a divorce.

In the fifty-sixth year of his age he was appointed proconsul of Cilicia, and his administration there gained him great honour. About this time the expectation of a breach between Cæsar and Pompey engaged the general attention. Crassus had been destroyed with his army some years before, in the war with the Parthians; and Julia, the daughter of Cæsar, whom Pompey had married, and who, while she lived, formed the cement of their union, had also died in childbed. Cæsar had put an end to the Gallic war, and reduced the whole province under the Roman yoke; but though his commission was near expiring, he seemed to have no thoughts of giving up his command and returning to the condition of a private subject. He pretended that he could not possibly be safe if he parted with his army, especially while Pompey held the province of Spain, the government of which had been continued to him for five years. This tendency towards a breach Cicero learned from his friends, as he was returning from his province of Cilicia. But as he foresaw the consequences of a war more clearly and fully than any of them, so his first resolution was to apply all his endeavours and authority to the mediation of a peace; though, in the event of a breach, he secretly determined to follow the fortunes of Pompey. He clearly foresaw, and indeed declared without scruple to his friends, that which side soever proved victorious, the war must necessarily end in a tyranny. The only difference, he said, was, that if their enemies conquered, they should be proscribed; if their friends, they would be slaves.

He had no sooner arrived in the city, however, than he fell, as he tells us, into the very flame of civil discord, and found the war in effect proclaimed; for the senate had just voted a decree that Cæsar should disband his army by a certain day, or be declared a public enemy; and his sudden march towards Rome had effectually confirmed it. In the midst of all this hurry and confusion, Cæsar was extremely solicitous about Cicero; not so much to gain him, for that was not to be expected, as to prevail with him to remain neutral. He wrote to him several times to this effect, and employed all their common friends to press him with letters on the subject, but in vain; for Cicero was impatient to join Pompey. In the mean time these letters give us a most sensible proof of the high esteem and credit in which Cicero was held at this time in Rome; when, in a contest for empire, which force alone was to decide, the chiefs on both sides were so solicitous to gain a man to their party who had no peculiar skill in arms nor talents for war. Pursuing, however, the result of all his deliberations, he at length embarked to join Pompey, who had been obliged to quit Italy some time before, and was then at Dyrrachium; and he arrived safely in the camp with his son, his brother, and his nephew, thus committing the fortunes of his whole family to the issue of the cause. After the battle of Pharsalia, in which Pompey was defeated, Cicero returned into Italy, and was afterwards received into great favour by Cæsar, who had now been declared dictator the second time, with Mark Antony as his master of horse. We may easily imagine, what indeed we find from his letters, that he was not a little disconcerted at the thoughts of an interview with Cæsar, and the indignity of presenting himself before a conqueror against whom he had been in arms; for although, upon many accounts, he had reason to expect a kind reception from Cæsar, yet he hardly thought his life, he says, worth begging, since what was given by a master might always be taken away again at pleasure. But at their meeting he had no occasion to say or do any thing below his dignity; for Cæsar no sooner saw him than he alighted, ran to embrace him, and walked with him alone, conversing very familiarly, for several furlongs.

Cicero, now in his sixty-first year, was at length forced to part with his wife Terentia, whose humour and conduct had long been disagreeable to him. She was a woman of an imperious and turbulent spirit; and though he had borne her perverseness in the vigour of health, and the prosperous state of his fortunes, yet, in declining life, and soured by a continual succession of mortifications from abroad, the want of ease and quiet at home became no longer tolerable to him. But he was immediately oppressed by a new and most cruel affliction, the death of his beloved daughter Tullia, who died in childbed soon after her divorce from her third husband Dolabella. She was about thirty-two years old at the time of her death; and, by the few hints which are left of her character, she appears to have been an excellent and admirable woman. She was most affectionately and piously attentive to her father, and, to the usual graces of her sex, added the more solid accomplishments of knowledge and polite letters, which qualified her to be the companion and delight of his age, and made her justly esteemed not only as one of the best, but the most learned, of the Roman ladies. His affliction for the death of this daughter was so great, that to shun all company as much as he could, he removed to Atticus's house, where he lived chiefly in his library, turning over every book he could meet with on the subject of moderating grief. But finding his residence here too public, and being exposed to more society than he was able to bear, he retired to Astura, one of his seats near Antium; a little island on the Latian shore, at the mouth of a river of the same name, and covered with wood and groves cut into shady walks, forming a scene altogether the fittest to indulge melancholy, and to afford a free vent to affliction. "Here," says he to Atticus, "I live without the speech of man. Every morning early I hide myself in the thickest of the wood, and never come out till the evening. Next to yourself, nothing is so dear to me as this solitude; and my whole conversation is with my books." Indeed his whole time was employed in little else than reading and writing, during Cæsar's administration, which he could never cheerfully submit to; and it was within this period that he drew up one of the gravest of those philosophical pieces which are still extant in his works.

Upon the death of Cæsar, Octavius, his nephew and heir, coming into Italy, was presented to Cicero by Hirtius and Pansa, with the strongest professions on the part of the young man that he would be governed entirely by his direction. Indeed Cicero thought it necessary to cherish and encourage Octavius, if for nothing else, to keep him at a distance from Antony; but he could not yet be persuaded to enter heartily into his affairs. He suspected his youth and want of experience, and that he had not strength enough to deal with Antony; and, above all, that he had no good disposition towards the conspirators. He thought it impossible he should ever be a friend to them; and indeed he was persuaded, that if ever he obtained the ascendency, his uncle's acts would be more violently enforced, and his death more cruelly revenged, than even by Antony himself. Accordingly, when Cicero at last consented to unite himself to Octavius's interests, it was with no other view than to arm him with a power sufficient to con-

trol Antony, yet so checked and limited, that he should not be able to oppress the republic.

In the midst of all this political bustle he still prosecuted his studies with his usual application; and, besides some philosophical pieces, now finished his book of Offices, or the Duties of Man, for the use of his son. However, he paid constant attention to public affairs, and missed no opportunities, but on the contrary did every thing that human prudence could suggest, for the restoration of the republic; indeed all the vigour with which the last effort was made in its behalf, was entirely owing to his counsels and authority. This appears from the memorable Philippics which from time to time he published against Antony, as well as from other monuments of antiquity. But all was in vain; for although Antony's army was entirely defeated at the siege of Modena, and many people were in consequence led to imagine that the war was at an end, and the liberty of Rome established, yet the death of the consuls Pansa and Hirtius in that action gave a fatal blow to all Cicero's schemes, and proved the immediate cause of the ruin of the republic.

Octavius having humbled the senate to his mind, marched towards Gaul to meet Antony and Lepidus, who had already passed the Alps, and brought their armies into Italy, in order to have a personal interview with him, which, in fact, had been privately concerted for settling the terms of a triple league, and dividing the power and provinces of Italy among themselves. The place appointed for this interview was a small island about two miles from Bononia, formed by the river Rhenus, which runs near that city. Here they met, and spent three days in close conference, adjusting the plan of their accommodation; and the last thing they settled was the list of a proscription of their common or individual enemies. This, as the writers tell us, occasioned much difficulty and warm contests among them, till each in his turn consented to sacrifice some of his best friends to the revenge and resentment of his colleagues. Cicero was at his Tusculan villa when he first received the news of the proscription, and of his being included in it at the instigation and to satisfy the vengeance of Antony. It was the design of the triumvirate to keep it a secret, if possible, till the very moment of execution, in order to surprise those whom they had destined to destruction, before they were aware of their danger, or had time to effect their escape. But some of Cicero's friends found means to give him early notice of this infamous compact, upon which he set forward to the sea-coast, with the design of transporting himself beyond reach of his enemies. There, finding a vessel ready, he immediately embarked; but the winds being adverse, and the sea uneasy to him, after he had sailed about two leagues along the coast, he was obliged to land, and spend the night on shore. By the importunity of his servants, however, he was forced on board again; but he soon afterwards landed at a country-seat of his, a mile from the shore, weary of life, and declaring he was resolved to die in that country which he had so often saved. Here he slept soundly for some time, till his servants once more forced him away in a litter towards the ship, having heard that he was pursued by Antony's assassins. They had scarcely departed when the assassins arrived at his house, and, perceiving that he had fled, immediately pursued and overtook him in a wood near the shore. Their leader was one Popilius Lenas, a tribune of the army, whose life Cicero had formerly defended and saved. As soon as the soldiers appeared, the servants prepared to defend their master's life at the hazard of their own; but Cicero commanded them to set him down and make no resistance. The assassins soon cut off his head and his hands, with which they returned to Rome as the most agreeable present to their savage and remorseless employer. Antony, who was then at Rome, received them with extreme joy, rewarded the murderers with a large sum of money, and ordered the head to be fixed upon the rostra between the two hands,—a sad spectacle to the city, and which drew tears from every eye.

If we take an impartial survey of Cicero's conduct and principles, avowed in his own epistolary correspondence, and trace him through all the labyrinths of his contradictory letters, we shall perhaps find more to blame than to admire; and discover that the desire of advancing his fortunes, and making himself a name, were, from his outset in life, the chief objects he had in view. The good of his country, and the dictates of a steady unyielding virtue, were not, as in Brutus and Cato, the constant springs of his actions. The misfortunes which befel him after his consulship developed his character, and showed him in his true colours: from that time to his death, pusillanimity, irresolution, and unworthy repining, tainted his judgment, and perplexed every step he attempted to take. He flattered Pompey and cringed to Cæsar, while in his private letters he abused both alternately and impartially. He acknowledges, in a letter to his friend Atticus, that, although he was at present determined to support the cause of Rome and liberty, and to bear misfortune like a philosopher, there was one thing which would gain him over to the triumvirs, and that was their procuring for him the vacant augurship; so pitiful was the bribe to which he would have sacrificed his honour, his opinions, and the commonwealth.

Cicero's death happened on the 7th of December, in the sixty-fourth year of his age, about ten days after the settlement of the first triumvirate. As an orator he is thus characterized by a popular writer: " In all his orations his art is conspicuous. He begins commonly with a regular exordium, and with much address prepossesses the hearers, and studies to gain their affections. His method is clear, and his arguments are arranged with exact propriety. In a superior clearness of method, he has an advantage over Demosthenes. Every thing appears in its proper place. He never tries to move till he has attempted to convince; and in moving, particularly the softer passions, he is highly successful. No one ever knew the force of words better than Cicero. He rolls them along with the greatest beauty and magnificence; and in the structure of his sentences is eminently curious and exact. He is always full and flowing, never abrupt. He amplifies every thing; yet though his manner is generally diffuse, it is often happily varied and accommodated to the subject. When an important public object roused his mind, and demanded indignation and force, he departs considerably from that loose and declamatory manner to which he at other times is addicted, and becomes very forcible and vehement. This great orator, however, is not without his defects. In most of his orations there is too much art, even carried to a degree of ostentation. He seems often desirous of obtaining admiration rather than of operating conviction. He is sometimes, therefore, showy rather than solid, and diffuse where he ought to have been urgent. His sentences are always round and sonorous. They cannot be accused of monotony, since they possess variety of cadence; but from too great a fondness for magnificence, he is on some occasions deficient in strength. Though the services which he had performed to his country were very considerable, yet he is too much his own panegyrist. Ancient manners, which imposed fewer restraints on the side of decorum, may in some degree excuse, but cannot entirely justify, his vanity."

There have been many editions of all Cicero's pieces, and many also of his whole works. Their multiplicity is so great that we can only refer those who may wish for

information in regard to them, to the works which have been published on the bibliography of the classics, particularly Dibdin's fourth edition. We may, however, mention shortly some of the most useful editions. These are, the edition of his treatises on Oratory, printed *in usum Delphini*, in 2 vols. 4to, in 1687; of his Letters, by Grævius, published in 1677, in 2 vols. 8vo; of his Orations, also by Grævius, published in 1699, in 6 vols. 8vo; and of his Philosophical Works, by Rath, published in 1808, in 6 vols. 8vo. One of the best editions of his whole works is that of Olivet, published at Paris in 1742, in 9 vols. 4to. The beautiful edition published at Glasgow in 1749, in 20 vols. 12mo, is a reprint of that of Olivet. Among the other editions of note, may be mentioned that of Manutianus, which is the *editio princeps*, Mediol. fol. 1498, 4 vols.; that of Paulus Manutius, which is deservedly held in high estimation, Venet. 1540–41, 10 vols.; that of R. Stephanus, Paris, 1543, 8 vols.; that of Elzevir, beautiful and correct, exhibiting the improved text of Gruter, Lugd. Bat. 1642, 10 vols.; those of Ernesti, Lipsiæ, 1737, Hal. Sax. 1758–74, one in 5 vols. and the last in 8; the beautiful and correct edition of Lallemand in 14 vols. 12mo, Paris, 1768; the magnificent, but as yet uncompleted, edition begun at Naples in 1777; and the Bipont edition, which professes to be formed on the basis of the most popular ones, without the introduction of either conjecture or novelty, 1780, 13 vols. Later than any of these is the edition of Orelli, Turic. 1826–1837, valuable not only on account of the accuracy of its text, but as containing the recovered portions or fragments of the celebrated treatise on government (*De Republica*), for which the world is indebted to the patient labour and sagacity of Signor Angelo Mai, librarian of the Vatican, formerly of the Ambrosian library at Milan. In a palimpsest volume, containing various treatises of St Augustin, this learned and ingenious person found that the original writing, of much greater antiquity, had consisted of the long-lost books of Cicero *De Republica*, of which nothing had been known in modern times except the few fragments which had been preserved in the writings of Macrobius, Lactantius, Augustin, Nonnius, and others. From these rescribed pages, a very considerable part of the first and second books of this interesting treatise was found so perfect as to be almost completely recovered by Signor Mai; and this he was enabled to publish in 1821, with copious notes and illustrations, with an accurate notice of all the chasms occurring from the loss of original leaves, and with such a restoration of the four remaining books as could be made from the less perfect fragments of the manuscript, and from the remains collected by Ligonius and other critics. This is perhaps the most valuable contribution which has been made to classical literature in modern times; and it is sufficient to immortalize the learned, sagacious, and indefatigable scholar to whom we are indebted for it; consisting, as it does, of no inconsiderable portion of that treatise which the contemporaries of the Roman orator and statesman all agreed in regarding as his masterpiece.

CICISBEO, an Italian term, synonymous with *cavalièr servente*, and used to signify a dangler about ladies. Formerly no married woman of fashion was to be seen in public without her cicisbeo, whose duty it was to attend upon her everywhere, and in short to act the part of the most devoted admirer. This practice is now fast declining. Though the office of cicisbeo has been the subject of frequent invective, it has not wanted its advocates and admirers. Among others, Baretti, in his "Account of the Manners and Customs of Italy," has endeavoured to vindicate it with much ingenuity—ascribing it to a spirit of gallantry derived from the age of chivalry, and much heightened and refined by the revival of the Platonic philosophy in Italy about the thirteenth century, and by the verses of Petrarch and his numerous imitators.

CICLUT, or CICLUCH, a strong frontier town of Dalmatia, situated on the river Narentha, in Long. 18. 22. E., Lat. 43. 29. N., and surrounded by walls built in the ancient manner.

CICOGNARA, LEOPOLD, COUNT. This eminent writer was born of a noble family at Ferrara in 1767, and distinguished himself in physical and mathematical science at Pavia, where he completed his academical career. In 1795 we find him settled at Modena, where he was employed by the government; and for some time he was its representative at Turin; but he resigned this post in 1808 on being appointed president of the academy of the fine arts at Venice. He was now in his true element, and published very important works connected with the fine arts. His treatise on the Beautiful appeared soon after his removal to Venice; and from 1816 to 1818 he published his great work "Storia della Scultura dal suo Risorgimento in Italia al Secolo di Napoleone," in 3 vols. folio. This excellent work gives a luminous view of the progress of modern sculpture, carrying down its history to our own times, and thus supplying the portions since the time of Winckelmann and D'Agincourt. He also produced a treatise on copper-engraving, "Memorie per servire alla Storia della Calcografia;" and the two magnificient folio volumes "On the Most Conspicuous Edifices of Venice" owe much of their value to his pen, though in this work he had the assistance of Selva and Diedo. His systematic catalogue of his own rich library, in two 8vo volumes, shows the immense collection he had formed of works illustrative of every branch of the fine arts, and the use he had made of them. In short, he may be regarded as one of the most learned and assiduous writers that ever handled such subjects. He also possessed considerable poetic powers, as appears by his first publication, "Le Ore del Giorno," published at Palermo in 1790; the beautiful and correct edition of Lallemand, in 14 vols. 12mo, Paris, 1768; and the magnificent but as yet uncompleted edition begun at Naples 1777. Cicognara died at Venice on the 5th March 1834. (T. S. T.)

CICUTA, hemlock, the juice of which was the famous κώνειον of the Athenians, used in the execution of criminals. Thus, too, perished Socrates, B.C. 399. (Plat. *Phæd.*)

CID, The, (from the Arabic *El Seid*, the Lord,) a name given to Rodrigo Diaz de Bivar, the national hero of Spain. See POETRY.

CIDARIS, a Persian word signifying a diadem or tiara, and used to denote the mitre of the high priest of the Jews. The rabbin admit no difference between the high priest's head-dress and that of other priests, except that the one was flat and in the form of a turban, while that worn by ordinary priests was somewhat peaked.

CIDER or CYDER, a vinous liquor made from the expressed and fermented juice of the apple. In England, the counties of Devon and Hereford are noted as the cider counties; but good cider is also produced in the counties of Gloucester, Monmouth, Worcester, Dorset, Somerset, and Cornwall. Normandy has long been known for the excellence of its cider; and considerable quantities are manufactured in other districts of France, and also in Belgium, Germany, and in North America.

In this country the manufacture of cider is almost entirely in the hands of the common farmer, so that little or nothing has been done either to improve the machinery, or bring science to bear on the processes which are followed. Hence much of the cider is of inferior quality, and much waste ensues in the manufacture. The apples for cider should only be gathered when fully ripe, as it is only then that they contain their full proportion of saccharine matter. As the apples are gathered they are laid in heaps, and are allowed to lie thus from 15 to 30 days in order to become fully ripe or mellow. They are then thrown (in this country) into a circular stone trough, round which a heavy circular stone is turned by means of one or two horses. When the apples

are thoroughly reduced to a pulp, the pulp is carried in pails to the screw-press and poured into square pieces of hair-cloth, the edges of the hair-cloth being so folded over the pulp as to prevent any escaping. The pulp is then subjected to pressure in the press when the juice escapes, leaving a solid cake. The juice is now transferred to casks, where it rapidly undergoes a process of fermentation, without requiring any addition; and in three or four days the process is completed, when it is drawn off into casks. The best cider is almost always that in which the process of fermentation has been most slowly conducted. When the fermentation has been rapid the cider is apt to run to acidity.

In France several manufacturers of cider have lately employed improved apparatus for mashing their apples, somewhat similar to that used for mashing the beet-root in the manufacture of sugar; and have also given special attention to the management of the process of fermentation. The quality of the cider is said to have been thereby greatly improved. The cake after its first pressure is sometimes broken up with water and subjected to a second pressure, and the juice it then yields furnishes, on fermentation, an inferior cider, which must be soon used, as it will not keep. Cider is not fit to be drunk till about three months after it is made. Good cider yields about 6 per cent. of alcohol on distillation, and thus contains nearly the same amount of alcohol as the ordinary bitter Indian ales; but the inferior kinds used by the labourers in Devon and Hereford do not contain above half that proportion. Cider appears to be a refreshing and healthful drink; and the natives of the counties in which it forms the ordinary drink are remarked to be nearly exempt from stone and from gravel complaints.

CIEZA or ZIEZA, a town of Spain, on the left bank of the Segura, province of Murcia, and 24 miles N.W. from the town of that name. Pop. about 6500. It has manufactures of coarse linens. On the opposite side of the river there are remains of a Roman town, supposed to be *Carteia*.

CIGAR. See TOBACCO.

CIGOLI, LODOVICO CARDI DA, a Florentine painter of the third epoch of that school, was born in 1559. He may be considered as the artist who taught the Florentine school the value of a finer chiaroscuro than it then possessed. His style was formed on that of Coreggio, though he failed in giving his pictures the mellow lucidness of that mighty master of colouring. Cigoli drew well, and had a good knowledge of perspective, in which he was instructed by Buontalenti, while he was the scholar of Santi di Tito. His finest pictures are in the churches of Florence and in the ducal gallery. The *Martyrdom of St Stephen* in the nunnery of Monte Domini, and his *St Albert* in S. Maria Maggiore; and above all his *St Peter healing the lame man* in the Vatican, are among his noblest productions. This last Sacchi considers next to Raphael's *Transfiguration*, and the *St Jerome* of Domenichino. Cigoli died in 1613. (T.S.T.)

CIGNANI, CARLO, an Italian painter, born at Bologna in 1628. He was the disciple of Albano. Pope Clement XI. nominated him prince of the academy of Bologna, and loaded him with favours. Cignani died at Forli in 1719. His cupola of La Madonna del Fuoco at Forli, representing Paradise, is an admirable work. His principal pictures are at Rome, Bologna, and Forli.

CILIA (Lat. *cilium*, an eye-lash), in *Anatomy*, the name given to minute hair-like organs found in various animals on the surfaces of certain tissues, and requiring the aid of lenses to discover their form. They were first observed on the bodies of infusorial animals, and appear to be their organs of motion. They are most conspicuous on the Ciliograde Medusaria, and on the gills of various mollusca. On the external surface of infusoria they were first noticed by Leeuwenhoek; but they have since been found not only in the invertebrata and cold-blooded vertebrata, but Parkinje and Valentin have demonstrated cilia to exist on the moist tissues of the higher types of animals—and they not only exist on the external surfaces of animals inhabiting water, but also in the alimentary system, the organs of respiration, and those of reproduction. Their office seems to be to produce motion in the fluids on such surfaces. Their form is generally that of elongated cones, but sometimes they are flattened filaments varying in length even in the same animal, from $\frac{1}{500}$th to $\frac{1}{10,000}$th of an inch. They are usually colourless and transparent, sometimes slightly coloured, and exist in a state of perpetual motion, but which is seldom rapid. See ZOOLOGY.

CILICIA, an ancient division of Asia Minor, bounded W. by Pamphylia, N. by the range of Mount Taurus, which separates it from Pisidia, Lycaonia, and Cappadocia, E. by Mount Amanus, which separates it from Syria, S. by the Mediterranean. The western portion of Cilicia, from its broken and hilly character, was called *Trachæa* or rough, while the eastern portion, which consists for the most part of continuous plains, was called *Campestris* or level. The former division was famed for its breed of horses, and for the noble cedars which grew in great abundance on its mountain slopes; the latter was well watered and highly cultivated, producing largely the various kinds of cereals, besides dates and other fruits. Reckoning from Coracessium to Rhossus, Cilicia has a sea-board of about 420 miles. The direct distance, however, between these two places is only about half that measurement.

Cilicia was the fourth satrapy in the arrangement of Darius, and its annual tribute consisted of 500 talents of silver and 360 of its famous horses.

In Cilicia Trachæa the only river of any importance is the Calycadnus (Gok-Su), which rises in Taurus, and flowing from W. to E., falls into the sea near Cape Zephyrium. Three rivers of considerable magnitude drain the levels of Cilicia Campestris, the Cydnus, the Sarus, and the Pyramus. The waters of the first of these have long been noted for their coldness, which in ancient times nearly proved fatal to Alexander the Great, and more recently caused the death of Frederick Barbarossa. The Sarus (the modern Sihun), rising in Cappadocia, falls into the sea after a very irregular course of about 200 miles chiefly in a S.W. direction. The Pyramus, or Jyhoon, the largest of the Cilician rivers, consists of two main streams, which rising in Cataonia, unite at Marash and flow into the sea in a direction almost parallel with the course of the Sarus. Between the mouths of these rivers is the famous Aleian plain, renowned in Grecian mythology as the scene of Bellerophon's wanderings. The mouth of the Pyramus became in course of time so silted up that the river shifted the lower part of its course, and now falls into the sea by an outlet 22 miles E. of the ancient mouth. The most important towns of Cilicia Trachæa were Coracessium, now Alaya, a strong natural fortress; Selinus, afterwards called Trajanopolis, from the name of Emperor Trajan, who died there; and Seleucia, of which the ruins only now remain. In Cilicia Campestris the most noteworthy cities were Tarsi or Tarsus, now Tersoos, the birthplace of the Apostle Paul, and a famous school of philosophy; Issus, where Alexander defeated Darius, B.C. 333; and Soli, afterwards called Pompeiopolis from Pompey the Great, the birthplace of Chrysippus the Stoic philosopher and the poets Philemon and Aratus.

According to the old Greek myths, the Cilicians (who were originally called Hypachæi) took their name from Cilix, the son of the Phœnician Agenor. They were originally governed by native kings, who successfully resisted the attempts of Crœsus and others to subdue them, and remained independent till the rise of the Persian empire. Even after their incorporation with that power they continued to be governed by their own princes. When Xerxes was organizing a fleet for the invasion of Greece, Cilicia contributed 100 galleys, which were placed under

the command of Syennesis, whose bravery is eulogized by Æschylus (*Pers.* 320).

If tradition may be believed, the Greeks began at a very remote period to settle in Cilicia. Historical evidence of their presence in the country, however, is wanting till the days of Alexander the Great. The natives gradually retired before them, and took refuge in the mountainous regions of the Trachæa, where they maintained themselves till the time of Cicero. After the downfal of Persia, Cilicia passed into the family of the Seleucidæ, by whom it was retained till Pompey reduced the Campestris to a Roman province. The mountaineers were not finally subdued till B.C. 52, in which year the proconsul Cicero took their stronghold Pindenessus—an exploit for which he was rewarded with a triumph on his return to Rome. After this the Trachæa continued to be governed by native princes till the reign of Vespasian, when it was reduced to a Roman province. The character of the Cilicians never stood very high among the ancients. By the Greeks and Romans, the Cilicians, Carians, and Cappadocians were classed together as the three bad Ks.

CILICIUM, in Hebrew antiquity, a sort of habit made of Cilician goat's hair, used by the Jews in times of mourning. It is the sackcloth of the Septuagint and Hebrew versions.

CIMABUE, GIOVANNI, one of the regenerators of the art of painting, was born at Florence in 1240. The early historians of art differ in the accounts they give of his education. Vasari maintains that his instructors were some Greeks who had been engaged to restore the ancient paintings in a Florentine church; while Lanzi denies this statement, and asserts that art was at this time better understood in Italy than in Greece. At the time that Cimabue appeared, the arts and sciences had fallen into neglect in consequence of the civil wars which had long desolated the peninsula. So highly valued were his efforts for the restoration of painting, that on one occasion an altar-piece, which he completed for a church in his native city, was inaugurated with a triumphal procession by his grateful countrymen. Some of Cimabue's works are still preserved in Florence, but his masterpieces are believed to be the frescoes in the church of St Francesco at Assisi. (For a critical estimate of Cimabue's works, and their influence on subsequent art, see article PAINTING.) In addition to the benefits which he conferred on painting by his contributions to it, Cimabue rendered most important service to it indirectly by discovering and fostering the genius of Giotto, the greatest of all his pupils. Cimabue died in 1300.

CIMAROSA, DOMENICO, a celebrated composer of music, was born at Aversa, in the kingdom of Naples, in 1754, and died at Venice on the 11th of January 1801. A priest, named Porzio, taught him the elements of music; and he learned singing under Aprile, and composition under Fenaroli in the Conservatory of Loretto. In 1773 he began to compose operas for the Italian theatres, and was eminently successful, even although he had to contend at Naples with the popular Paesiello. In 1787 he was engaged by the court of St Petersburg, where he composed several operas, a mass, and a cantata, besides about 500 detached pieces. His health suffering from the climate, he left Russia in 1792, and went to Vienna. There he composed, in 1792, his best opera, *Il Matrimonio Segreto*—full of beauty and originality. He returned to Naples in 1793. The style of this great artist is distinguished by facility, elegance, and simplicity. His fecundity was prodigious. His works consist of 69 operas, a mass, two requiems, one dixit, several litanies, a Te Deum, four oratorios, and three cantatas, besides the 500 detached pieces above mentioned. In his opera *Il fanatico per gli antichi Romani*, composed in 1775 for the Teatro dei Fiorentini at Naples, he was the first to introduce vocal trios and quartetts in the course of the action. (G.F.G.)

CIMBRI, an ancient Celtic nation, inhabiting the northern parts of Germany. They are said to have been descended from the Asiatic Cimmerians, and to have taken the name of Cimbri when they changed their old habitations. When they first became remarkable, they inhabited chiefly the peninsula now called Jutland, and by the ancients *Chersonesus Cimbrica.* About 113 years B.C. they left their peninsula, with their wives and children, and joining the Teutones, a neighbouring nation, took their journey southward in quest of a better country. They first fell upon the Boii, a Gallic nation, situated near the Hercynian forest; but here they were repulsed, and obliged to move nearer the Roman provinces. The republic, being then alarmed at the approach of such multitudes of barbarians, sent an army against them, under the consul Papirius Carbo. On the approach of the Roman army, the Cimbri made proposals of peace, which the consul pretended to accept; but having thrown them into a disadvantageous situation, he treacherously attacked their camp. His perfidy was rewarded as it deserved; the Cimbri flew to arms, and not only repulsed the Romans, but, attacking them in their turn, utterly defeated them, and obliged the shattered remains of their forces to conceal themselves in the neighbouring forests. After this victory, the Cimbri entered Transalpine Gaul, which they quickly covered with slaughter and desolation. Here they continued five or six years, when another Roman army, under the consul Silanus, marched against them; but this general met with no better success than Carbo had done. His army was routed at the first onset, and all *Gallia Narbonensis* was in consequence exposed to the ravages of these barbarians.

About 105 years B.C. the Cimbri began to threaten the Roman empire itself with destruction; and the Gauls marched from all parts, with a design to join them in the invasion of Italy. The Roman army was commanded by the proconsul Cæpio and the consul Mallius; but as these two commanders could not agree, they were advised to separate and divide their forces. This advice proved ruinous to the whole army. The Cimbri immediately fell upon a strong detachment of the consular army, commanded by M. Aurelius Scaurus, which they cut off to a man and made Scaurus himself prisoner. Mallius greatly intimidated by this defeat desired a reconciliation with Cæpio, but was haughtily refused. He moved nearer the consul, however, with his army, in order that the enemy might not be defeated without his having a share in the action. The Cimbri, imagining by this movement that the commanders had made up their quarrel, sent ambassadors to Mallius with proposals of peace; and as they could not avoid passing through Cæpio's camp, he ordered them to be brought before him; but finding they were empowered to treat only with Mallius, he could scarcely be restrained from putting them to death. His troops, however, forced him to confer with Mallius about the proposals sent by the barbarians; but as Cæpio proceeded to the consul's tent against his will, so he opposed him in everything, contradicted him with great obstinacy, and insulted him in the grossest manner. The deputies, on their return, acquainted their countrymen that the misunderstanding between the Roman commanders still subsisted; upon which the Cimbri attacked the camp of Cæpio, and the Gauls that of Mallius, both of which were forced, and the Romans slaughtered without mercy. Eighty thousand citizens and allies of Rome, with forty thousand servants and sutlers, perished on that fatal day. In short, of the two Roman armies, only ten men, with the two generals, escaped, to carry the news of this dreadful defeat. The conquerors destroyed all the spoil, pursuant to a vow they had made before the battle. The gold and silver they threw into the Rhone, then drowned the horses they had taken, and put to death all the prisoners.

The Romans were thrown into the utmost consternation

on the news of so terrible an overthrow. They saw themselves threatened with a deluge of Cimbri and Gauls, numerous enough to overrun the whole country; but they did not on that account despair. A new army was raised with incredible expedition, no citizen who was able to bear arms being exempted. On this occasion, also, fencing-masters were first introduced into the Roman camp; by which means the soldiers were soon rendered in a manner invincible. Marius, who enjoyed at that time a high reputation on account of his victories in Africa, was chosen commander, and waited for the enemy in Transalpine Gaul; but they had resolved to enter Italy by two different routes; the Cimbri over the eastern, and the Teutones and other allies over the western Alps. The Roman general, therefore, marched to oppose the latter, and defeated the Ambrones and Teutones with great slaughter. The Cimbri, in the meantime, entered Italy, and struck the whole country with terror. Catullus and Sylla attempted to oppose them; but their soldiers were so intimidated by the fierce countenances and terrible appearance of these barbarians, that nothing could prevent their flying before them. Rome was now totally defenceless; and had the Cimbri only marched briskly forward, they would undoubtedly have become masters of the city; but not having heard of the defeat of their allies by Marius, they waited in expectation of being joined by the Ambrones and Teutones, till the senate had time to recal him to the defence of his country. By their order he joined his army to that of Catullus and Sylla, and upon this junction he was declared commander-in-chief. The Roman army consisted of 52,300 men. The cavalry of the Cimbri were no more than 15,000, but their foot seemed innumerable; for, being drawn up in a square, they are said to have covered thirty furlongs. The Cimbri attacked the Romans with the utmost fury; but being unaccustomed to endure the heats of Italy, they soon began to lose their strength, and were easily overcome. They had put it out of their power to fly; for, that they might keep their ranks the better, they had, like true barbarians, tied themselves together with cords fastened to their belts, so that the Romans made a terrible havoc of them. The battle, therefore, was soon over, and the whole day employed in the most unsparing butchery. A hundred and twenty thousand were killed on the field of battle, and sixty thousand taken prisoners. The victorious Romans then marched to the enemy's camp, where they had a new battle to fight with the women, whom they found even more fierce than their husbands. From their carts and waggons, which formed a kind of fortification, they discharged showers of darts and arrows on friends and foes without distinction; and, finding themselves about to be overpowered, they first suffocated their children in their arms, and then put an end to their own lives. The greater part of them hanged themselves on trees. One was found hanging at a cart with two of her children at her heels. Many of the men, for want of trees and stakes, tied strings in running knots about their necks, and fastened them to the tails of their horses, and the horns and feet of their oxen, in order to strangle themselves in that way; and thus the whole multitude was destroyed.

The country of the Cimbri, which, after this terrible catastrophe, was left a mere desert, was again peopled by the Scythians, who, being driven by Pompey out of the space included between the Euxine and the Caspian Sea, marched towards the north and west of Europe, subduing all the nations they met with in their way. They conquered Russia, Saxony, Westphalia, and other countries as far as Finland, Norway, and Sweden. It is pretended that Woden, or Odin, their leader, traversed so many countries and endeavoured to subdue them only with a view to excite the people against the Romans; and that the spirit of animosity which he had excited operated so powerfully after his death, that the northern nations combined to attack the empire, and never ceased their incursions until it was totally subverted.

CIMMERII, a nomad people of antiquity who dwelt near the Palus Mæotis, in the Tauric Chersonese, and in Asiatic Sarmatia. They are said to have desolated Asia Minor prior to the time of Homer; and in their second invasion they penetrated as far westward as Æolis and Ionia, captured Sardis the capital of Lydia B.C. 635, in the reign of Ardys, and continued in possession till they were driven out of Asia by Alyattes, the grandson of that sovereign. (Herod. i. iv.; Strab. i.)

This was also the name of a mythical people, represented by Homer as inhabiting a remote region of mist and darkness; but they are localized by later writers near Lake Avernus, and also in the Tauric Chersonesus, and in Spain. Their country was fabled to be so gloomy, that, to indicate great obscurity, the expression "Cimmerian darkness" became proverbial; and Homer, according to Plutarch, drew his images of hell and Pluto from the gloomy and dismal region inhabited by the Cimmerii.

CIMOLIA TERRA (Cimolite), a species of clay much esteemed by the ancients as a cataplasm in erysipelas and other inflammations. They also used it as fuller's earth, for cleansing cloth. The ancients obtained the Cimolia Terra in several islands of the Archipelago, but particularly from Cimolus (now Argentiera or Kimoli), whence it derived its name. It is still plentiful in those islands; and the Turks, who believe in the virtues ascribed to it by the ancients, mould it into small cakes, which are stamped with the seal of the Grand Signior. Cimolite is of a soft crumbly texture; has a white or pearly-gray hue; adheres firmly to the tongue; and when thrown into water, moulders to a fine powder. These are the characters of the ancient *terra cimolia*. It yielded to Klaproth of silica 62, alumina 23, oxide of iron 1·25, and water 12; sp. gr. 2. It is believed to be formed by the decomposition of trachite.

CIMON, son of Miltiades. See ATTICA, pp. 201-2. The life of Cimon has been written by Plutarch and by Cornelius Nepos.

CIMON of Cleonæ, a famous painter who flourished about B.C. 460, the inventor of *catagrapha*, or drawing in perspective. (Plin. viii. 8.) See CATAGRAPHA.

CINALOA, or SINALOA. See MEXICO.

CINCHONA, PERUVIAN or JESUITS' BARK, is the dried bark of several species of the genus Cinchona, belonging to the Linnean class and order Pentandria Digynia, and to the natural order Cinchonaceæ. (See BOTANY, vol. v., p. 196.) This bark has for a couple of centuries retained its reputation as a nearly infallible remedy or specific in the cure of agues or intermittent fevers. It is not known how the native Peruvians first acquired the knowledge of the virtues of this bark, though many stories are told to account for it; such as, that a native was cured of an ague by drinking from a pool into which a cinchona tree had fallen, to the water of which it had imparted its virtues, &c. But if certain natives had so discovered its virtues, the knowledge of this must not have spread far, as even a century after its reputation was established in Europe, Humboldt and Bonpland found the natives around Loxa, whence the best supplies were derived, still ignorant of its value in agues. Its virtues were first made known in Europe in the year 1640 in consequence of its having cured of an intermittent fever the wife of the viceroy of Peru, the Conde del Chinchon; and from this circumstance the bark was afterwards known as the bark of Chinchon, Cortex Chinchonæ, variously corrupted, according to the pronunciation, into *Chinchina*, *Kinkina*, *Quinquina*. Shortly after its introduction into Spain, the Jesuits had the bark sent to them by their brethren in Peru, and keeping the secret of its source to themselves spread it over Europe. In consequence of its being alone procurable through the Jesuits, it received the name of Jesuits' bark.

Cinchona.

On its first introduction into Europe it was vehemently opposed by the medical profession, till its cause was espoused by Dr Roland Sturm of Antwerp in 1659. An Englishman of the name of Talbot having discovered its source a few years later, and succeeded in curing with it the Dauphin of France, the Prince of Condé, and many persons of rank—sold his secret to the French government for a knighthood, L.1600, an annuity of L.80, and a monopoly of the trade for ten years. Its price at this time reached the enormous sum of L.5 sterling per ounce.

For more than a century after the discovery of its virtues the jealousy of the Spaniards foiled all attempts to investigate the botanical history of the cinchona barks; and even at the present day, notwithstanding the investigations of La Condamine, Jussieu, Ruiz and Pavon, Humboldt and Bonpland, Poppig, and even the latest naturalist who has visited these regions, Weddell, much remains to be ascertained regarding the species of trees which yield the several varieties of bark. Weddell has done more than others to determine accurately the exact species which yield several of the varieties of bark; and has, in addition to the external characters of the barks, given in his elaborate work drawings of the appearance of fine sections of the several barks under the microscope. The subject has been still further investigated in this country by John Eliot Howard, Esq.; and it is to be hoped that in a few years the whole of the different varieties of bark will be able to be referred to their proper species. Chemistry now lends a powerful aid to all such investigations; for as the essential and powerful remedial agent in these barks is found to reside in an alkaloidal substance, which in the most valued barks is termed quinine, the less valued barks are found to contain less of this and a greater proportion of a less valued alkaloid, cinchonine; or the quinine is quite superseded by another similar principle called aricine.

The cinchona trees are met with in the elevated valleys of the Andes, in Colombia, Peru, and Bolivia, from the 11th degree of N., to the 20th degree of S. latitude, and from 1200 to 10,000 feet above the level of the sea. The bark is collected from May to November. The trees are usually cut down and peeled; and the fresh shoots which spring from the roots are ready for cutting after six or eight years. The Indians, however, to save themselves trouble, often peel the bark from the tree while still standing, and so destroy the tree for ever. The thinner bark from the small branches curls up in drying, and forms quills: the thicker bark from the larger branches and stems remains in flat pieces.

The curative properties of Peruvian bark depend on the presence in the bark of peculiar alkaloidal substances, which vary in quality and kind in the different varieties of barks. The most valued of these is quinine; and hence in modern medicine this substance, combined with sulphuric acid, when it forms the sulphate of quinine, has almost entirely superseded the use of the bark itself in the cure of agues and other diseases. Other alkaloidal principles, similar but scarcely so powerful in action, exist in the cinchona barks, as cinchonine, aricine, cinchovatine, quinidine, &c. All these have more or less powerful febrifuge properties; and the first especially might with propriety be substituted for the more expensive quinine in hospital and dispensary practice, and in the army and navy. So much have these chemical preparations of the bark superseded the use of the crude bark itself, that the latter is now very rarely used in medical prescriptions; while these alkaloidal principles, from their small bulk, from their not overloading the stomach with a great mass of inert matter, and from their unvarying uniformity of strength, may be given in doses and in cases where the crude bulky powder could not be used. Almost every disease which shows a tendency to recur in regular fits or paroxysms is alleviated or removed by the use of Peruvian bark, or of its alkaloids quinine and cinchonine. Hence the value of these not only in agues (intermittent fevers), but in neuralgia, tic douloureux, hooping-cough, &c. Quinine and cinchonine are also powerful tonics, and are given with the best effects in recovery from debilitating fevers and diseases, in gangrene, &c. (J. S—K.)

Cincinnati.

CINCINNATI, a city in the state of Ohio, North America, capital of the county of Hamilton, on the north side of the Ohio river, 113 miles S.W. of Columbus; Lat. 39. 5. 54. N., Long. 84. 27. W. It was founded in 1789 by emigrants from New England and New Jersey, and incorporated in 1819. Pop. in 1800, 750; in 1830, 24,831; in 1840, 46,338; in 1850, 115,436. This is the largest inland city of the United States, and in point of population ranks sixth. It stands near the eastern extremity of a pleasant valley about 12 miles in circumference, surrounded by hills, and divided into two nearly equal parts by the Ohio. The ground on which the city is built consists of two plains, one about 60 feet above the other. Except along the margin of the river, the city is regularly laid out, the streets crossing each other at right angles, many of them adorned with fine edifices, and beautifully shaded with trees. It contains about 80 churches, many of them elegant buildings, 3 colleges, 4 medical schools, a law school, a female college, several female seminaries, 6 classical and numerous public schools; besides various libraries, and literary, philosophical, and charitable institutions. Among the public buildings are several public halls, the county and city courts, mercantile exchange, observatory, museum, 4 theatres, gas and water works, &c. The manufactures of Cincinnati are very varied, embracing almost every branch of industrial employment. There are numerous distilleries, breweries, tanneries, soap-works, foundries, iron-works, provision-curing establishments, &c. The total number of the manufacturing and industrial establishments in the city was about 3400, employing about 32,850 persons. Cincinnati is very favourably situated for commerce, being on the banks of the Ohio, and having railroads and canals extending in every direction. The Miami canal and the Ohio division of the Wabash and Erie canal connect the Ohio with Lake Erie, a distance of 251 miles. The Little Miami railroad and its branch-lines to Cleveland (255 miles); the Cincinnati Hamilton and Dayton, and its branch-lines to Sandusky (218 miles); and a number of others, completed or in progress, render Cincinnati the chief centre of the railroad system of the Western States. It has direct railway communication with every lake-port from Chicago to Niagara; with Albany, Boston, New York, Philadelphia, and Baltimore; and will soon be connected with Charleston, Savannah, Mobile, New Orleans, and St Louis. It has also telegraphic communication with every large city from Maine to Florida, and from the Atlantic to beyond the Mississippi. The river trade is carried only chiefly in steam-boats with New Orleans, Pittsburg, St Louis, and other ports. The arrivals of steam-boats during the year ended 31st August 1852, amounted to 3675, of which 219 were from New Orleans, 574 from Pittsburg, and 218 from St Louis. The departures during that year were 3611; of which 326 were for New Orleans, 498 for Pittsburg, and 241 for St Louis. The shipping owned within the district in 1850 was 17,181 tons, of which 16,906 were propelled by steam. A detailed account of the trade and commerce of Cincinnati in 1852 will be found in *Hunt's Merchants' Magazine* for November 1852. The city is governed by a mayor, recorder, and three councillors for each of the seven wards into which the city is divided. It has a separate judiciary, and also a commercial court, specially instituted to try causes arising between merchants. There are 8 daily newspapers in Cincinnati, all of which issue weekly editions, and 1 a tri-weekly edition, 22 weekly papers, 1 semi-monthly, and 14 monthly periodicals. Near the city are two beautiful suburban villages, Mount Auburn and Walnut Hills; the latter being the seat of Lane Seminary, a theological institution

Cincinnatus ‖ Cinnamon.

under the New School Presbyterians. Four miles N.W. of the city are 2 fine cemeteries, the one occupying about 100, and the other 40 acres. In the vicinity of Cincinnati the cultivation of the vine is extensively carried on, for which the soil and climate are well adapted.—(See *Gazetteer of United States*, 1853; De Bow's *Resources of the South and West*, 1853; *Hunt's Magazine*, &c.)

CINCINNATUS, Lucius Quintius, a celebrated Roman, reduced to poverty (according to the legend) by having to pay a heavy bail on account of the flight of his son Cæso. He is said to have been ploughing his farm on the banks of the Tiber when called to fill the consulship, and was twice chosen (B.C. 458 and 439) under the same circumstances to be dictator. During his first dictatorship, which he resigned at the end of 16 days, he defeated the Æqui, and afterwards the Volsci, and procured the honourable recal of his son from banishment. In his second dictatorship he was chiefly occupied with thwarting the machinations of Spurius Mælius. See Roman History.

CINEAS, a Thessalian, the minister and friend of Pyrrhus king of Epirus. He was sent to Rome after the battle of Heraclea to sue for a peace, but was foiled in his mission through the eloquence of Appius Cæcus. He told Pyrrhus that the Roman senate was a venerable assembly of kings; and that to fight with them was to fight against another Hydra. He was a man of consummate address, and possessed a memory so retentive that the day after his arrival at Rome he could call every senator and knight by name. His last diplomatic mission was to Sicily, B.C. 278; and with his death the fortunes of Pyrrhus began to decline.

CINERITIOUS, resembling ashes in colour or consistence; and hence this epithet has sometimes been applied to the cortical part of the brain.

CINNABAR, the native red sulphuret of mercury, the most prolific ore of that metal. *Factitious* cinnabar, or vermilion, is made by heating 100 parts of mercury with 16 of sulphur in an iron vessel, and subliming the compound. The sublimate, when reduced to powder, is of a beautiful scarlet colour. It is the *minium* of antiquity. See Chemistry.

CINNAMON. The cinnamon of commerce is chiefly produced in the island of Ceylon in the East Indies, from the *Laurus Cinnamomi* of botanists, the *Kooroondoo-gaha* of the Singhalese, a plant which appears to have flourished in that island from the earliest period. We learn from Scriptural history (Exodus xxx. 23) that this spice was employed by the Hebrews in their religious ceremonies; and there can be little doubt that their supplies were derived from the Arabian merchants who traded between the Red Sea and the East.

When the commerce between the western and eastern world was opened by way of the Cape of Good Hope, cinnamon formed a valuable item in the precious commodities received from the regions of the sun in exchange for calamancoes, metal work, and silver coin. The Portuguese had their attention drawn to this spice at an early period; and there can be no doubt that their chief and perhaps sole reason for forming a settlement in Ceylon was to secure a monopoly of the trade in this article, since Colombo, their first fort, and afterwards the European capital of the island, possessed no other claim for their choice than its proximity to the cinnamon lands of that island.

The Singhalese never attempted to cultivate this shrub, but were content to leave it in its indigenous state, and draw their supplies of the spice from the jungles of the sea-board and the forests of the interior. No sooner, however, had the Portuguese established a footing in the island on the west coast, and erected a stone fort at Colombo, than they commenced the exploration of the adjacent country where they had learnt the bulk of the cinnamon grew. It was found in greatest abundance as far as Negombo on the N., and to Morotto on the S. of Colombo, and scattered more thinly over a great portion of the western and southern coasts.

Cinnamon.

The little taste evinced by the Portuguese for agricultural pursuits, added to the continual state of warfare in which they found themselves involved with the native sovereigns of the island, proved a serious obstacle to the cultivation of this spice, which, indeed, appears to have received no care until the Dutch took possession of Ceylon, when they soon turned their attention to the subject. By clearing the cinnamon tracts from jungle and weeds, and draining the ground, they succeeded in producing a finer quality of bark; and by means of honorary distinctions and immunities from taxation granted to the *Chalias* or *Cinnamon Caste*, induced them to prepare the spice for the market in a far superior manner.

The cinnamon lands, or gardens as they are termed, were thus formed by the Dutch at Kaderani, Welliserre, Ekelle, Marandahn, and Moorotto, and are still existing at those places. They were very unequal in size and productiveness, and together covered an extent of 12,000 acres. The cultivation and trade in this article were preserved in the hands of the government by the most severe enactments; the offence of injuring a plant, or cutting the smallest fragment of the bark, was punishable with death; and the entire management and control of the gardens vested in the office of the "*Mahabadde*" or Chalia caste, whose duties and privileges were made the subject of a long code of laws.

The cinnamon trade of Ceylon was greatly extended under the Dutch government; and we read that, in the middle of the eighteenth century, as many as 1500 bales were required for the Indian government, 200 bales for Persia, 400 bales for the Coromandel coast, and 8000 bales for Europe; which, at 88 lb. the bale, gives a total of 900,000 lb. The only mart for the sale of this and other spices in Europe at that period was Amsterdam. The following table of cinnamon sold at the Dutch capital from 1692 to 1792 will be a safe guide to the consumption of Europe during that period:—

	Quantity Sold.	Average Price per lb.
1692	375,000	4s. 1¾d.
1702	300,000	3 9
1722	425,000	4 3½
1742	350,000	3 9¼
1762	350,000	9 10
1782	200,000	17 4
1792	250,000	14 7

The right of trading in cinnamon after the capture of the island by the British, was left in possession of the East India Company, who received annually from the local government a quantity ranging between 4000 and 4500 bales of 100 lb. each, at a stipulated price. This contract was terminated in 1821, after which the spice continued to be shipped to England by the Ceylon government, and there sold on their account to the extent generally of 4500 bales, which yielded a nett income of about L.97,000.

In the year 1833, the monopoly in this spice, so long enjoyed by the crown, was abandoned, and the culture and trade thrown open to the public; a duty of 3s. 6d. per lb. being levied on the export of the spice. The government stock of cinnamon in the island was disposed of by public sales held monthly, as well as future crops from their gardens, until 1840, when they commenced the sale of those properties by monthly auctions, realizing for their price sums varying between L.5 and 7s. the acre. Since the gardens came into the possession of private capitalists, great improvements in the cultivation and preparation of the spice have taken place. Manuring, pruning, and draining have been successfully resorted to on an extensive scale, and the yield of cinnamon per acre has, in some cases, been brought up from 50 lb. to 500 lb.

In 1837 the first imports of cinnamon from Java into Europe took place; and, influenced by this new rival, the government reduced the export duty on the best cinnamon

to 2s. 6d. per lb. The inferior sorts had been two years previously reduced to that amount.

In 1841 the duty was lowered to 2s., and in 1843 to 1s. on all qualities. Subsequent reductions were made, first to 8d. then to 4d. per lb., and at present it is exported free of all duty. These continued concessions to the trade do not appear to have had so favourable an effect upon the consumption of the spice in Europe and America, (to which localities the demand has been confined during the present century), as might have been looked for. The sales of cinnamon in London during the nine years previous to the opening of the Ceylon trade, averaged 4138 bales annually; during the nine years succeeding that period, the deliveries of spice averaged about 5000 bales yearly. During the seven years ending 1852, the shipments from Ceylon averaged 5100 bales. From 1829 to 1833, the value of cinnamon in London ranged between 10s. and 5s. the lb. From 1834 to 1843, the London price fluctuated from 9s. 3d. to 3s. 9d. Since that period the highest price paid has been 6s., and the value at present ranges between 2s. 6d. and 1s.

In 1837, the Dutch government imported their first parcel of cinnamon from Java, amounting to 3951 lb. In 1839 the import was 16,312 lb. In 1842 it reached 124,696 lb., and in 1845 its highest point of 180,000 lb.; since which it has sensibly fallen off. Its early value varied from 6½d. to 5s. 6d. per lb., but it has since declined to prices ranging from 3d. to 3s. 4d.

A more decided rival to cinnamon has been the cassia of the Malabar coast and China, which has become an important article of our trade since 1817. In that year the imports into London amounted to 1745 chests, worth L.10 to L.13 per cwt. It has since been imported to the extent of 36,000 chests, but the value has declined to L.5 and L.3 per cwt. The countries to which this is chiefly exported are Russia, Prussia, Spain, and the Levant.

Cinnamon is chiefly employed in the manufacture of chocolate, confectionary, liqueurs, and medicines, and was at one time largely used in religious ceremonies on the continent of Europe, and for fumigations. For both of these latter purposes, however, cassia has been largely substituted, the low price at which it has been produced having been far below the cost of cinnamon when free from export duty.

The cinnamon of Ceylon, as now imported, is produced from three distinct sources; from the late government gardens; from private or inferior plantations; and lastly, from the forests of the interior. The average yield from these sources for the last four years of the monopoly was:—government gardens, 1453 bales per annum; from uncultivated plantations, 1135 bales; from forests, 1456 bales. The yield of these under the free-trade system may be stated at 3300 bales from the gardens; 1700 bales from the private lands; whilst the forests are rarely searched for spice at the present low prices. The finest cinnamon, both in flavour and appearance, comes from the government gardens, and the worst from the forests, where it is found thick in quill, of a dark colour, and of a bitter, acrid flavour. The best is that which is of a bright clear colour, of a soft, sweet, aromatic taste, not gritty in the mouth, and which is not thicker than stout paper. A pipe or quill of fine cinnamon should be smooth, clear brown, without blemish, and contain three or four layers of bark within it.

Cinnamon thrives best in a light sandy soil of some depth, free from stagnant water. A hot damp atmosphere, such as prevails along the sea-board of Ceylon, is highly favourable to the proper development of the plant; and without these desiderata it is impossible to produce a spice of good quality. It is the absence of these which has rendered the cinnamon recently cultivated in Java so far inferior to the Ceylon article.

The cinnamon plant, if left in its natural state, becomes a tree of considerable size, and in this state it is usually met with in the Ceylon forests. These trees are also to be seen in South America, although Spain ships larger supplies of Ceylon spice to that continent. The trees and large bushes bear blossoms, and the seeds, shaped like a small acorn, yield an agreeable oil, which used to be highly valued by the Singhalese, and kept for burning in the lamps of the royal palace of their kings.

Plants are reared from the seed, and placed in well cleared land, on the first setting in of the periodical rains, in clusters of five, of which about nine hundred cover an acre. These young plants require shading from the sun, and daily watering during the first two dry seasons; after which they will thrive unaided, and yield a small crop in the fourth year; arriving at maturity, if well tended, in the twelfth year; after which there does not appear to be any limit to their duration. The cinnamon bushes left by the Portuguese two centuries since still continue to bear abundantly.

The crops are taken off twice in the year at the setting in of the monsoon rains. The first or great harvest is usually secured between the first week in June and the middle of August. The second or small harvest is taken in during November and December. If a cinnamon garden be properly tended, there will not be a weed visible upon it. Drainage is highly necessary, and a little shade from lofty trees at wide intervals is desirable, to protect the plants during the hot dry months.

The operation of stripping the bark from the straight cinnamon sticks is performed by none but those of the *Chalia* caste, who are very expert at the work. Good "peelers," as these men are called, will prepare, with the aid of their family, from 80 to 100 lb. of spice in a month; for which they are paid at the rate of 3d. or 4d. the lb., according to quality. The bark being sorted or made into quills or pipes, forty inches in length, containing three or four layers inside, and being first slowly dried in the shade, is afterwards exposed for three days to the sun. At the end of two months the spice may be packed in gunny, a coarse native sacking, and shipped. It is made up in bales of 100 lb. each, having generally the native name of the garden in which it was produced marked on the outside of the bales.

The ordinary yield of the old government gardens is about 30 lb. of spice per acre; a few of the finest will produce nearly 100 lb., and by the aid of high cultivation, as much as 500 lb. Good cinnamon land is worth L.10 an acre; though it may be planted and brought into full production for about L.7.

An essential oil of great aroma is obtained by distillation from the broken and imperfect bark. When properly made, and produced from a good quality of spice, this oil is worth 3s. an ounce in the London market; but the great bulk is inferior, and sells at about 8d. It is used in perfumery, pharmacy, and confectionary, as a substitute for the powdered spice.—(*Parliamentary Reports;* Rybiero's *Ceylon; Ceylon Magazine.*) (J. C—R.)

CINTRA, a town of Portugal, province of Estremadura, 14 miles N.W. of Lisbon, with about 4000 inhabitants. It stands at the foot of a stupendous rocky mountain, and is remarkable for the picturesque beauty of its situation and the salubrity of its climate, which render it a favourite resort of the wealthier inhabitants of Lisbon. On one of the adjacent summits stands the Penha convent; and on another are the ruins of a Moorish castle. It has also an ancient royal palace. The convention, by which the French were allowed to leave Portugal without molestation, was signed at Cintra, August 22, 1808.

CINQUE PORTS (*i. e.*, the five ports), five havens on the south-eastern coast of England, opposite France, and thus called by way of eminence, on account of their importance as safeguards against invasion. These comprise Hast-

ings, Romney, Hythe, Dover, and Sandwich; to which were afterwards added the two ancient towns of Winchelsea and Rye. These places were anciently deemed of so much importance in the defence of the kingdom against invasion, that they received royal grants of particular privileges, on condition of providing during war a certain number of ships at their own expense. They are governed by a warden with the title of Lord Warden of the Cinque Ports, and each had the privilege formerly of returning to parliament two members under the title of Barons of the Cinque Ports; but since 1831 this privilege has been confined to Hastings, Dover, and Sandwich. We are told by Camden that William the Conqueror appointed the first warden of the Cinque Ports; but their charters are traced to the time of Edward the Confessor. The salary of the Lord Warden is L.3000 a-year. (See Chitty's *Commercial Law*, vol. ii. p. 12.)

CINYRA, in *Jewish Antiquity*, a musical instrument of the lyre kind. This and the Hebrew *kinnor*, which is generally translated *cithara* or *lyra*, are probably the same. It was usually made of wood. Josephus says that the *cinyra* of the temple had ten strings, and was played with a plectrum; and in another place he mentions some made of a mixed metal called *electrum*. (*Antiq.* vii. 12-3.)

CIOTAT, LA, a maritime town of France, department of Bouches-du-Rhône, arrondissement and 16 miles S.E. of Marseilles, on the west side of a bay of the Mediterranean. It is surrounded by old walls, and is regularly and well built. The port, protected by a mole and defended by a fort, is commodious and secure, and has a lighthouse with a lantern 82 feet above the level of the sea. It has a considerable trade in wine, oil, and dried fruits. Pop. 4200.

CIPHER, or Cypher (from the Arabic *sifr*, devoid of, empty), one of the Arabic characters used in computation, and formed thus, 0.

Cipher is also a kind of enigmatic character composed of several letters interwoven; as the initial letters of a person's name. Anciently, merchants and tradesmen not being allowed to bear family arms, in lieu thereof bore their ciphers, or initials of their names, artfully interwoven about a cross. These frequently occur on tombs and other monuments.

Cipher also denotes certain characters used in writing secret despatches, so that their contents shall be understood by none but those between whom the characters are agreed on.

The *scytala* of the Spartans has been regarded as a species of cipher. The scytalæ were two wooden cylinders exactly alike, one of which was kept by the ephori, the other by the general of the army sent on any expedition against the enemy. Whenever any secret orders were to be sent to the general, a narrow slip of parchment was wound close round the scytala, and on this the instructions were written. When taken off the cylinder only broken or single letters appeared; but their connection was at once restored by the general on applying the parchment to the scytala in his possession. Polybius says that Æneas Tacticus had collected together twenty different manners of writing, so as not to be understood by any but those in the secret; and that these methods were partly invented by himself, and partly in use before his time. Trithemius, Baptista Porta, Vigenère, and P. Niceron, have written expressly on the subject of ciphers.

The art of writing in cipher has given rise to another art—that of deciphering or unravelling the meaning of such writing. The rules of deciphering are different in different languages. By observing the following, any one may read a common cipher written in English.

1 Observe the letters or characters that most frequently occur, and set them down for the six vowels, including *y*, and of these the most frequent will generally be *e*, and the least frequent *u*.

2. The vowels that most frequently come together are *ea* and *ou*.

3. The consonant most common at the end of words is *s*, and the next frequent is *r* or *t*.

4. When two similar characters come together, they are most likely to be the consonants *f*, *l*, or *s*, or the vowels *e* or *o*.

5. The letter that precedes or follows two similar characters is either a vowel, or *l*, *m*, *n*, or *r*.

6. In deciphering, begin with the words that consist of a single letter, which will be either, *a*, *I*, *o*, or *&*.

7. Then take the words of two letters, one of which will be a vowel. Of these words the most frequent are, *an*, *to*, *be*, *by*, *of*, *on*, *or*, *no*, *so*, *as*, *at*, *if*, *in*, *is*, *it*, *he*, *me*, *my*, *us*, *we*, *am*.

8. In words of three letters, there are most commonly two consonants. Of these words the most frequent are, *the*, *and*, *not*, *but*, *yet*, *for*, *tho'*, *how*, *why*, *all*, *you*, *she*, *his*, *her*, *our*, *who*, *may*, *can*, *did*, *was*, *are*, *has*, *had*, *let*, *one*, *two*, *six*, *ten*, &c. Some of these, and words of two letters, will be found in every sentence.

9. The most common words of four letters are, *this*, *that*, *then*, *thus*, *with*, *when*, *from*, *here*, *some*, *most*, *none*, *they*, *them*, *whom*, *mine*, *your*, *self*, *must*, *will*, *have*, *been*, *were*, *four*, *five*, *nine*, &c.

10. The most usual words of five letters are, *their*, *these*, *those*, *which*, *where*, *while*, *since*, *there*, *shall*, *might*, *could*, *would*, *ought*, *three*, *seven*, *eight*, &c.

11. Words of two or more syllables frequently begin with double consonants, or with a preposition; that is, a vowel joined with one or more consonants. The most common double consonants are, *bl*, *br*, *dr*, *fl*, *fr*, *gl*, *gr*, *ph*, *pl*, *pr*, *sh*, *sb*, *sp*, *st*, *th*, *tr*, *wh*, *wr*, &c.; and the most common prepositions are, *com*, *con*, *de*, *dis*, *ex*, *im*, *in*, *int*, *mis*, *per*, *pre*, *pro*, *re*, *sub*, *sup*, *un*, &c.

12. The double consonants most frequent at the end of long words are, *ck*, *ld*, *lf*, *mn*, *nd*, *ng*, *rl*, *rm*, *rn*, *rp*, *rt*, *sm*, *st*, *xt*, &c.; and the most common terminations are, *ed*, *en*, *er*, *es*, *et*, *ing*, *ly*, *son*, *sion*, *tion*, *able*, *ence*, *ent*, *ment*, *full*, *less*, *ness*, &c.

By applying these rules, any common cipher written in English may be deciphered; and, *mutatis mutandis*, a cipher written in any language may be evolved by an application of the principle on which these rules are constructed.

CIPPUS, in *Antiquity*, a low column, with an inscription, erected on the high road or elsewhere, to show the way to travellers, to serve as a boundary, or to mark a grave. It was sometimes highly ornamented, as seen in the specimens in the British Museum.

CIPOLIN (Ital., *cipolla*, an onion), a green Italian marble with irregular concentric white zones.

CIPRIANI, Giovanni Battista, well known for his numerous designs engraved by Bartolozzi, was born at Florence in 1727. He settled in England, and there he died in 1785. He was one of the original members of the Royal Academy of Design.

CIRCARS, Northern, an extensive province of Hindustan, lying on the western side of the Bay of Bengal. It is a narrow slip of territory, extending from 15. 2. to the 20th degree of N. Lat., but is little more than one degree in breadth. The sea bounds it on the E. along a coast 470 miles in length, from the port of Mootapilly to the town of Maloud in Orissa, on the borders of the Chilca Lake. From about 50 to 70 miles inland it is divided from the province of Hyderabad by a range of small detached hills, extending to the banks of the Godavery; and it is separated from Gundwana to the N. of that river by the great ridge of the Eastern Ghauts, impassable except in some few depressions for horse or wheel-carriages. From Goomsur the same unbroken chain curves to the eastward, reducing the breadth of the province at this point

to a narrow tract of about 18 miles. Towards the south the small river Gondlacama, which empties itself at Mootapilly, separates this territory from the district of Ongole.

The area of the Circars is 30,060 square miles, of which it is estimated that only one-fifth is in cultivation or fallow, twice that portion in pasture, and the remainder occupied by woods, water, towns, barren hills, and a sandy waste three miles in breadth, which borders the whole extent of the coast. The country for about 35 miles inland is a level plain, with only two remarkable interruptions in its greatest length along the shore. Beyond this about 15 miles farther inland, and parallel to it, the country is much more elevated, being agreeably variegated with hills easy of access, and remarkably fertile. Beyond these tracts of plain and hilly ground, to the north of the Godavery, a still higher region extends close to the great ridge of mountains which stretch far inland.

The grand divisions of this province are properly five. Of these the first is Guntoor, the most southerly division, bounded on the north by the river Kistnah, which, after running a curve of 600 miles from the Balaghaut hills, near the coast of Malabar, separates this province on the north from the second division, namely, Masulipatam. Rajahmundry is the third division, succeeded in a northerly direction first by Vizagapatam and lastly by Ganjam. These divisions, which are of comparatively modern date, were introduced by the British to supersede the original distribution of the territory into the five Circars of Cicacole, Rajahmundry, Ellore, Condapilly, and Guntoor.

The climate of the Northern Circars, though it has a general resemblance to that of Hindustan north of the Kistnah, is well distinguished by local peculiarities arising from its maritime situation, and the extent and position of the inland hills. The S.W. monsoon usually sets in about the middle of June with a westerly wind, and continues with moderate showers until the latter end of August, which is the period of the small grain harvest. In October it is succeeded by a variable season, ushering in the N.E. monsoon, with cooler weather and greater abundance of rain. This continues to the middle of November, when it generally ceases, and is succeeded by a strong north-easterly wind, tempered by the mild influence of the sea over which it blows. The harvest for rice and bajree, which are the great productions of the country north of the Godavery, finishes about the middle of this latter season, early in January; and in like manner the vernal equinox terminates the harvest south of that river for the different species of maize as well as of other grains and pease. Then commences the hot season, which is always moderate towards the northern extremity of the Circars, near Ganjam, owing to the constant breezes from the sea. On the south the hot season is moderated for two months by sea-breezes from the south blowing along the shore; but afterwards, until the period of the rains, the wind blowing over a parched loose soil of great extent, and especially over the almost dry and sandy bed of the Kistnah, becomes so heated that it raises the thermometer for an entire week to 105, and frequently to 110 degrees. In the hilly regions the air is in a highly noxious state; and throughout the different seasons of the year the hill fever, which is prevalent, is frequently fatal to strangers. It is generally ascribed to the state of the atmosphere, contaminated with the exhalations of a fertile soil, pent up in valleys, or impeded in its circulation by the luxuriant growth of plants, or by the trees with which the villages are surrounded. All these provinces along the coast have a sandy soil, which improves gradually towards the hills; but seldom produces more than one crop annually, except in localities enjoying an abundant supply of water. The country is well irrigated by running streams, many of which are divided artificially into canals, and conducted into tanks and reservoirs; thus being rendered subservient to cultivation. Within the last few years the government have appropriated considerable sums to the purpose of extending the system of irrigation by means of the waters of the Godavery and the Kistnah. Through the advantages which in this respect it enjoys, the province abounds in all the different sorts of grain which have been already mentioned: it is properly the granary of the Carnatic during the N.E. monsoon. Fruits, roots, and greens are scarce, or reared with difficulty, to the south of the Godavery; nor towards the north are they so excellent as in some other provinces. Sugar, cotton, and tobacco are largely cultivated. Salt is manufactured on the coast, and in such abundance as greatly to exceed the home demand. The forests of Rajahmundry, from the commencement of the hills, along the banks of the Godavery, yield an inexhaustible supply of the best and largest teak timbers; and if proper use were made of this advantage, an article would be procured of great importance to commerce. The cocoa and the palmyra, or, in the more northerly provinces, the tree which produces the gum-arabic, are the materials from which are constructed those unwieldy vessels with two masts, called doonies, averaging from 60 to 300 tons each. The domestic animals found in this province are chiefly sheep and the larger species of horned cattle. The neighbouring sea and its numerous inlets abound with almost every species of Indian fish, together with some that are common to Europe, such as mullet, sole, and the pomphlet, a small fish resembling a turbot.

Cotton is the staple produce, and from it are fabricated cloths of different degrees of fineness. The muslins of Masulipatam, and other places within the Circars, formerly in high esteem both at home and abroad, have been nearly superseded by the irresistible competition of British fabrics. The coarser plain cloths, which are made to the north and south of the Godavery, and coloured with chay root (which is the madder of the East, and grows in most perfection in the pure sands annually overflowed by the Kistnah,) are in great demand. Woollen carpets are manufactured at Ellore, and silks at Burrampore. But these are rather objects of curiosity than of any great general advantage; as is also the art of painting or inlaying ivory and black wood in the cabinet work at Vizagapatam. Ship-building is carried on extensively in the ports of Coringa and Narsapore, the two principal mouths of the Godavery. Here ships of 500 tons are built, and about 50,000 tons of small craft are employed in the coasting trade.

The native inhabitants of the Northern Circars, with the exception of some thousand Mohammedans found chiefly in the principals towns, are wholly Hindus. They are composed of the two nations of Telinga and Orissa, formerly divided from each other by the Godavery, but, since their union under the same government, amalgamated to some extent with each other, as well as with some of the neighbouring tribes. They have each their peculiar dialect, apparently of the Sanscrit language, as well as their peculiar rites, customs, and national traits. The four great castes or divisions of the people are common in both countries, but with less deviations from original institutions in Orissa, where Brahminical abstinence from animal food is very general among all the higher tribes. The Brahmins continue to enjoy their pre-eminence and consideration among the other classes. The Rachewars, Rowars, and Velmas, of which denominations the principal Zemindars are composed, affect the warlike character and manners of Rajpoots. The Rachewars are of the ancient race of the Orissa sovereigns, who were forced to fly before the conquering arms of the Mohammedans from the plains to the highland woods. The Rowars, or Worians, being petty chieftains of the military tribe, were enabled, after the Mohammedan conquest, to acquire an independent jurisdiction in the moun-

Circassia. tainous tract to the west of Cicacole. The Velmas are of Telinga origin; and being driven from the Carnatic in the year 1662 by the Mohammedans, they established themselves on the borders of the Kistnah. The remainder are husbandmen, cow-herds, weavers, artificers, all of the Sudra or last great caste. The retail dealers form a third class. The entire population of the Circars, according to the last census, was 4,284,187.

It was not till the year 1471 that the Mohammedans carried their arms to the Northern Circars. In 1541 they conquered Condapilly; and nine years afterwards they extended their conquests over all Guntoor, and the districts of Masulipatam. But the conquerors appear to have acquired only a very imperfect possession of the country, as it was again conquered from the Hindu princes of Orissa about the year 1571, during the reign of Ibrahim Kootub, Shah of Hyderabad or Golcondah. In 1687 these provinces, with the empire of Hyderabad, were added to the extensive empire of Aurungzebe. But this monarch was too busily employed in conquering the larger provinces of the Deccan, and curbing the Mahratta power, to bestow due care on his conquest. Nizam ul Moolk, appointed viceroy of the Deccan, and who in that character exercised the sovereign power which subsequently he usurped, reformed the administration of the revenues and the civil and military establishment. He was succeeded by his third son Salabut Jung, who, being indebted for his elevation to the French East India Company, granted them in return for their services the district of Condavir or Guntoor, and soon afterwards the other Circars. In 1759, by the conquest of that great commanding bulwark, the fortress of Masulipatam, the dominion of the maritime provinces on either side, from the river Gondegama to the Chilca Lake, was necessarily transferred from the French to the British. But they left them under the administration of the Nizam, with the exception of the town and fortress of Masulipatam, which were retained by the English East India Company. In 1765 Lord Clive obtained from the Mogul a grant of four of the Circars, which in the following year was confirmed by a treaty entered into with Nizam Ali, who had by this time superseded Salabut Jung in his authority. The remaining Circar of Guntoor devolved to the East India Company in 1788. (E. T.)

CIRCASSIA. The name of Circassia is given to all that western part of the Caucasian territory which is situated on the Black Sea, and bounded by the lands of the Cossacks, the Caucasians, the Lesghians, the Georgians, the Imeretians, and Mingrelians. This district, however, includes not only Circassia proper, but also the great and little Kabardah, Abasia, and the land of the Ossetes. The Circassians inhabit only that part of the country which is bounded by the Black Sea, and the rivers Sotsha, Laba, and the lower Kouba. The territory of Circassia towards the S.W. is exceedingly mountainous, and includes within its limits the Elburz, the Mainevari, and several of the loftiest parts of the Caucasian range. Towards the N.W. the mountains gradually decline in elevation; and the range of the Black Mountains between the Black Sea and the Kouba consists of a number of rounded hills, very moderate in height. Towards the N. and the N.E., a great number of small rivers descend rapidly from the mountains, and form in their course many pleasant and fertile valleys. On the coast of the Black Sea, along the river Kouba, and even in many of the interior parts of the country, several Russian forts have been erected in order to maintain the power of the Czar in these regions. The climate in the north-western part of Circassia is very insalubrious; as the water of the rivers, which are generally broad and shallow, frequently becomes stagnant in hot weather, and produces fatal fevers. In the more elevated portions of the country situated to the S.E., where the atmosphere is colder, the climate is much more favourable to health.

The Circassians, or Tschirkessians, are termed by themselves Adighé, or the noble. In the patriarchal simplicity of their manners, the mental qualities with which they are endowed, the beauty of form and regularity of feature by which they are distinguished, they surpass most of the other tribes of the Caucasus. They have long been celebrated for their warlike and intrepid character, their independence, their hospitality to strangers, and that love of country which they have manifested in their determined resistance to an almost overwhelming power during the period of a long and desolating war. They exhibit in their manners a strange mixture of chivalrous sentiment and of savage customs. The government under which they live is a peculiar form of the feudal system. The free Circassians are divided into three distinct ranks, the princes or *pschi*, the nobles or *uork*, (Tartar *usden*), and the peasants or *hokotl*. Like the inhabitants of the other regions of the Caucasus, they are also divided into numerous families, tribes, or clans, some of which are very powerful, and carry on war against each other with great animosity. The slaves, of whom a large proportion are prisoners of war, are generally employed in the cultivation of the soil, or in the domestic service of some of the principal chiefs.

The will of the people is acknowledged to be the supreme source of authority; and every free Circassian has a right to express his opinion in those assemblies of his tribe in which the questions of peace and war, almost the only subjects which engage their attention, are brought under deliberation. The princes and nobles, the leaders of the people in war, and their rulers in peace, are only the administrators of a power which is delegated to them. Having no written laws, the administration of justice is regulated solely by custom and tradition; and in those tribes professing Mohammedanism, by the precepts of the Koran. The most aged and respected inhabitants of the various *aouls* or villages frequently sit in judgment, and their decisions are received without a murmur by the contending parties. The Circassian princes and nobles are professedly Mohammedans; but in their religious services many of the ceremonies of their former heathen and Christian worship are still preserved. The great body of the people have remained faithful to the worship of their ancient gods, Shible, the god of thunder, of war, and of justice, Tleps, the god of fire, and Seosseres, the god of water and of winds. Although the Circassians possess minds capable of the highest cultivation, the arts and sciences, with the exception of poetry and music, are completely neglected. They possess no written language. The wisdom of their sages, the knowledge they have acquired, and the memory of their warlike deeds, are preserved in verses, which are repeated from mouth to mouth and descend from father to son.

The education of the young Circassian is confined to riding, fencing, shooting, hunting, and such exercises as are calculated to strengthen his frame, and prepare him for a life of active warfare. The only intellectual duty of the *atalik* or instructor, with whom the young men live until they have completed their education, is that of teaching them to express their thoughts shortly, quickly, and appropriately. One of their marriage ceremonies is very strange. The young man who has been approved by the parents, and has paid the stipulated price in money, horses, oxen, or sheep, for his bride, is expected to come with his friends fully armed, and to carry her off by force from her father's house. Every free Circassian has unlimited right over the lives of his wife and children. Although polygamy is allowed by the laws of the Koran, the custom of the country forbids it, and the Circassians are generally faithful to the marriage bond. The respect for superior age is carried to such an extent, that the young brother rises from his seat when the elder enters an apartment, and is silent when he speaks. Like all the other inhabitants of the Caucasus, the

Circassians are distinguished for two very opposite qualities. the most generous hospitality, and implacable vindictiveness, Hospitality to the stranger is considered one of the most sacred duties. Whatever be his rank in life, all the members of the family rise to receive him on his entrance, and conduct him to the principal seat in the apartment. The host is considered responsible with his own life for the security of his guest, upon whom, even although his deadliest enemy, he would inflict no injury while under the protection of his roof. The chief who has received a stranger, also grants him an escort of horse to conduct him in safety on his journey, and confides him to the protection of those nobles with whom he may be on friendly terms. The law of vengeance is no less binding on the Circassian. The individual who has slain any member of a family is pursued with implacable vengeance by the relatives, until his crime be expiated by death. The murderer may, indeed, secure his safety by the payment of a certain sum of money, or by carrying off from the house of his enemy a newly-born child, bringing it up as his own, and restoring it when its education is finished. In either case, the family of the slain individual may discontinue the pursuit of vengeance without any stain upon its honour. The man closely followed by his enemy, who, on reaching the dwelling of a woman, has merely touched her hand, is safe from all further pursuit so long as he remains under the protection of her roof. The opinions of the Circassians regarding theft resemble those of the ancient Spartans. The commission of the crime is not considered so disgraceful as its discovery; and the punishment of being compelled publicly to restore the stolen property to its original possessor, amid the derision of his tribe, is much dreaded by the Circassian who would glory in a successful theft. The greatest stain upon the Circassian character is the custom of selling their children. The Circassian father willingly parts with his daughters, many of whom are bought by Turkish merchants for the harems of eastern monarchs. No degradation is implied in this transaction, and the young women themselves are generally willing partners in it. However contrary this custom may be to the ideas of Christian nations, it is certain that none of the more revolting features of American slavery are practically connected with it. Herds of cattle and sheep constitute the chief riches of the inhabitants. The princes and nobles, from whom the members of the various tribes hold the land which they cultivate, are the proprietors of the soil. Although the Circassians are desirous of devoting their attention to commerce, the warlike attitude which they are compelled, by the presence of the Russians, to maintain, has hitherto prevented them from cultivating any of the arts of peace.

The early periods of Circassian history are exceedingly obscure. Several Greek colonies appear to have been established at a remote period upon the coasts of the Black Sea, which were inhabited by savage tribes noted for their piratical expeditions. By these colonies commercial activity and regular government were to some extent introduced into that wild and uncultivated region. To them the Romans afterwards succeeded, who maintained their authority during the period of their power and prosperity. In the twelfth and thirteenth centuries, the princes of Georgia were successful in reducing Circassia to the condition of a province of that kingdom. Thamar, one of the Georgian princes, is said by some to have been the first to introduce Christianity among the inhabitants, while by others it is maintained that the Christian faith was the prevailing religion from the fifth century. The Circassians having succeeded in the fifteenth century in throwing off the Georgian yoke, many of them settled on the coasts of the sea of Azof, where, coming in contact with the Tartars, they were subdued by the khans of the Crimea. In the middle of the sixteenth century, the Russian Czar, Ivan I., having married a Circassian princess, assisted the people to throw off the Tartar yoke, and became master of a considerable portion of the country. But the Russian monarchs do not appear to have regarded its conquest as a matter of much importance, until the time of Peter the Great. That powerful monarch perceiving how much the possession of the Caucasus would contribute to his political and commercial influence in western and central Asia, made an unsuccessful attempt to reduce it permanently under his dominion. Catherine II. pursued a similar line of policy. Georgia having been harassed by the successive invasions of the Persians and Turks, the prince of that country at last threw himself under the protection of the Russians, and became tributary to their power. The river Kouba being afterwards fixed as the southern boundary of the Muscovite empire, the Russians became ambitious of extending their dominion uninterruptedly to the extreme limits of Georgia The Circassians, meanwhile, surrounded by Mohammedan nations, visited frequently by Turkish merchants, and gained over by the impressive eloquence of a fanatical devotee, the sheik Mansur, had embraced the faith of Islam, and acknowledged the Sultan as chief of their religion In the wars which now took place between the Russians and the Turks, the latter used every exertion, by exciting the fanatical feelings of the Circassians against the infidels, to induce them to harass the Russians by frequent incursions into their territory. After having experienced the various fortunes of war, the Turks were worsted, and compelled by the treaty of Adrianople in 1829 to cede a considerable portion of their territory to the Czar. Assuming a right of political sovereignty which they had never possessed, Circassia was included in this cession. The Circassians refusing to acknowledge the right of the Sultan (whom they had never recognised as their sovereign) thus to dispose of their country, were now exposed to the hostility of the Russians, who determined to become masters of the territory on the coasts of the Black Sea, and indeed of the whole Caucasian region, by force of arms. This was the origin of that remorseless war which has been carried on with so much animosity under various leaders to the present day, and has cost the Russians an incredible amount of blood and treasure, and which is still apparently as far from ultimate settlement as it was at its commencement. See CAUCASUS.

CIRCE, a mythical sorceress, daughter of Sol and Perseis, celebrated for her skill in magic and her knowledge of poisonous herbs. She was sister to Æetes king of Colchis, and to Pasiphäe the wife of Minos. She married a Sarmatian prince of Colchis, whom she murdered to obtain the kingdom. She was expelled by her subjects, and carried by her father to an island called Ææa, upon the coast of Italy. Ulysses, on his return from the Trojan war, visited her coast; and all his companions, who ran headlong into pleasure and voluptuousness, were changed by Circe's potions into swine. Ulysses, who was fortified against all enchantments by a herb called *moly* which he had received from Mercury, went to Circe and demanded, sword in hand, the restoration of his companions to their former state. She not only complied, but welcomed the hero with marks of signal favour. In this voluptuous retreat Ulysses had by Circe one son called Telegonus, or according to Hesiod, two named Agrius and Latinus. For one whole year Ulysses forgot his glory in Circe's arms. At his departure the nymph advised him to descend to hell, and to consult the seer Tiresias concerning the fates that attended him. Circe also metamorphosed her rival Scylla, and Picus king of the Ausonians.

CIRCEII, a town of Latium, at the foot of Mons Circeius, and a short distance from the sea. It was originally colonized by the Romans in the reign of Tarquin the Proud, who deemed the position of the city favourable for commerce and for repressing the inroads of the Volsci. From its foundation till the date of the Latin War, B.C. 340, it seems to have been at one time subject to the Romans, at another to have espoused the cause of the Volsci, and sometimes to have been independent of either power. After the Latin War it was recolonized by the Romans; but it continued gradually to decline till the emperors Tiberius and Domitian, attracted to it by the pleasantness of its situation and the excellence of its oysters, erected villas in the neighbourhood. The ruins of the old city of Circeii are still distinctly visible on the Monte della Cittadella, about two miles from the sea.

CIRCENSIAN GAMES, a general term under which was comprehended all combats exhibited in the Roman circus, in imitation of the Olympic games in Greece. Most of the feasts of the Romans were accompanied with Cir-

censian games; and the magistrates and other officers of the republic frequently presented the people with these exhibitions in order to procure their favour. The great games (*Ludi Romani* or *Magni*) were held during several days from the 4th to the 12th of September. See CIRCUS.

CIRCLE, in *Geometry*, a plane figure comprehended by a single curved line called its circumference, every part of which is equally distant from a point called the centre. Consequently all straight lines drawn from the centre to the circumference are equal to each other.

CIRCLES *of the Sphere* are such as cut the mundane sphere, and have their periphery either on its movable surface, as the meridians; or in another immovable, conterminous, and equidistant surface, as the ecliptic, equator, and its parallels.

CIRCLES *of Altitude* or *almucantars*, are circles parallel to the horizon, having their common pole in the zenith, and diminishing as they approach the zenith.

Diurnal CIRCLES are immovable circles, supposed to be described by the several stars, and other points of the heavens, in their diurnal rotation round the earth, or rather, in the rotation of the earth round its axis. The diurnal circles are all unequal; the equator is the largest.

Horary CIRCLES, in *Dialling*, are the lines which show the hours on dials; though these be not drawn circular, but nearly straight.

CIRCLES *of Latitude*, or *Secondaries of the Ecliptic*, are great circles parallel to the plane of the ecliptic, passing through its poles, and through every star and planet. They are so called because they serve to measure the latitude of the stars, which is nothing but an arc of one of these circles intercepted between the star and the ecliptic.

CIRCLES *of Longitude* are several lesser circles, parallel to the ecliptic; still diminishing as they recede from it. On the arcs of these circles the longitude of the stars is reckoned.

CIRCLE *of Perpetual Apparition*, one of the lesser circles, parallel to the equator, described by any point of the sphere touching the northern point of the horizon, and carried about with the diurnal motion. All the stars included within this circle are always visible above the horizon.

CIRCLE *of Perpetual Occultation*, another lesser circle at a like distance from the equator, containing all those stars which never appear in our hemisphere. The stars situated between these circles alternately rise and set at certain times.

Polar CIRCLES are immovable circles, parallel to the equator, and at a distance from the poles equal to the greatest declination of the ecliptic. That next the north pole is called the Arctic, and that next the south pole the Antarctic.

Druidical CIRCLES, a name given to certain ancient inclosures formed by rude stones circularly arranged; as that of Stonehenge near Salisbury. These, it is now generally supposed, were temples, and also places of solemn assemblage for councils or elections, and seats of judgment.

CIRCLES of the Empire, the provinces or principalities of the German empire, which had a right to be present at the diets.

CIRCUIT, in *Law*, signifies the periodical progress of a legal tribunal for the sake of carrying out the administration of the law in the several provinces of a country. It has long been applied to the journey or progress which the judges have been in the habit of making twice every year, through the several counties of England, to hold courts and administer justice, where recourse could not be had to the king's court at Westminster. The country, including Wales, is now divided into eight circuits, viz., the Home, the Norfolk, the Midland, the Oxford, the Western, the Northern, the North Wales, and the South Wales circuit. For a short period the insolvency commissioners made circuits three times a-year, but in 1847 the duties of the circuits were transferred to the new county courts.

In Scotland the judges of the supreme criminal court, or High Court of Justiciary, form also three separate circuit courts, consisting of two judges each; and the kingdom, with the exception of the Lothians, is divided into corresponding districts, called the Northern, Western, and Southern Circuits. In certain burghs of each circuit two courts are held in the year, in spring and autumn, called Circuit Courts. One more is now held at Glasgow during the Christmas recess.

Ireland is divided into the North-East and the North-West Circuits, the Home Circuit, and those of Leinster, Connaught, and Munster.

CIRCULAR, in the form of a circle; circumscribed by a circle; spherical, &c. &c. It is also applied to a letter or paper, of which a copy is sent to several persons on some common business.

CIRCULAR *Instruments*, a general name for those astronomical and nautical instruments used for measuring angles, in which the graduation extends round the whole circumference, or to 360°.

CIRCULAR *Numbers* are those whose powers terminate in the roots themselves; as 5 and 6, whose squares are 25 and 36.

CIRCULAR *Sailing* is the method of sailing by the arc of a great circle. See NAVIGATION.

CIRCUM, a Latin prefix of many English words, signifying *around* or *about*. It corresponds to the Greek *peri* or *amphi*, as in *perimeter*, *amphitheatre*.

CIRCUMCELLIONES, or CIRCELLIONES, a furious and sanguinary set of fanatics in the fourth century, composed of peasants and rustics, who espoused the cause of the Donatists against the emperor Constantine, and went about with women as abandoned as themselves, filling the province of Africa with slaughter, rapine, and burnings, and inflicting on the persons of the adverse party the most atrocious cruelties. They were called *circumcelliones* because they hovered, vagrant like, about the cottages (*cellæ*) of the peasants, having no fixed residence of their own; and styled themselves *agonistici* or combatants, pretending that they were combating the devil. These wretches were utterly regardless of their lives, and when there was occasion they would face death with the greatest alacrity. They first appeared amid those terrible commotions that ensued when Constantine, A.D. 316, ordered the temples of the Donatists in Africa to be taken from them, banished the seditious bishops, and put others to death. Some have accused the Donatists of encouraging them in their enormities; but it does not appear on any good evidence that the bishops, or at least the more sensible of them, approved or instigated their proceedings. Constantine endeavoured in vain to repress their outrages; and the storm continued to increase till it seemed to threaten a civil war. The laws against the Donatists were repealed, A.D. 321. But the Circumcelliones were not subdued—for in the succeeding reign, when Constans attempted to heal this deplorable schism, and Donatus opposed a reconciliation, they still contended furiously in support of the party whose cause they had espoused. In the time also of Gratian, when that emperor deprived the Donatists of their temples, the Circumcelliones acted as the soldiery of the Donatists, and undoubtedly prevented the vigorous execution of the laws enacted against them, as proved by the subsequent prosperity of the Donatist community in Africa.—(Mosheim's *Ecclesiastical History*—Reid's edition.)

CIRCUMCISION, the act of cutting off the prepuce or foreskin; a Jewish and Mohammedan rite.

Circumcision was the seal of a covenant between God and Abraham. It was in the year of the world 2178 that Abraham, by divine appointment, circumcised himself and all the males of his family; from which time it became an hereditary practice among his descendants.

The ceremony, however, was not confined to the Jews, although it originated with them. Herodotus and Philo Judæus observe, that it obtained also among the Egyptians and Ethiopians. Herodotus says that the custom was very

ancient among each people; so that it was impossible to determine which of them borrowed it from the other. The same historian relates, that the inhabitants of Colchis also practised circumcision; and hence he concludes that they were originally Egyptians. He adds, that the Phœnicians and Syrians were likewise circumcised; that they borrowed the practice from the Egyptians; and, lastly, that a little before the time when he wrote, circumcision had passed from Colchis to the people living near Thermodon and Parthenius. (Herodot., ii. 104.)

Marsham is of opinion that the Hebrews borrowed circumcision from the Egyptians, and did not introduce the rite in compliance with the direct command of Heaven. Diodorus Siculus and Herodotus are cited by him as evidences on his side. This latter proposition seems directly contrary to the testimony of Moses, who tells us that Abraham, though ninety-nine years of age, was not circumcised till he had received the express command of God for the performance of the rite. The arguments on both sides may be seen in one view in Spencer *de Legibus Hebræorum.*

Among the Jews, the time for performing this rite was the eighth day, that is, six full days after the child was born. The law of Moses ordained nothing with respect to the person by whom, the instrument with which, or the manner how, the ceremony was to be performed; the instrument however was generally a knife of stone. The child was usually circumcised at home, where the father or godfather held him in his arms, while the operator, taking hold of the prepuce with one hand, cut it off with the other; a third person held a bowl, filled with sand, to catch the blood; then the operator applied his mouth to the part, and, having sucked the blood, spat it into a bowl of wine, and threw a styptic powder upon the wound (Othon. *Lex Rabb.* p. 133.) This ceremony was usually accompanied with great rejoicings and feasting; and at this time the child received his name in presence of the company. The Jews invented several superstitious customs at this ceremony, one of which consisted in placing three stools—one for the operator, the second for the person who held the child, and the third for Elijah, who, as they supposed, assisted invisibly at the ceremony.

The Jews distinguished their proselytes into two sorts, according as they were circumcised or not: those who submitted to this rite were looked upon as children of Abraham, and obliged to keep the laws of Moses; the uncircumcised were only bound to observe the precepts of Noah, and were called *Noachidæ.*

A sort of circumcision has also been found to exist in various parts of the Indian Seas and Pacific Ocean.

CIRCUMFERENCE, in a general sense, denotes the line or lines bounding a plane figure. However, it is generally used in a more limited sense for the curve line which bounds a circle, otherwise called a periphery; the boundary of a rectilineal figure being expressed by the term perimeter.

CIRCUMFERENTOR, an instrument used by surveyors for taking angles.

CIRCUMFLEX, in *Grammar*, an accent serving to note or distinguish a syllable of an intermediate sound between acute and grave, and generally somewhat long. The Greeks had three accents, the acute, the grave, and the circumflex, marked respectively thus, ´, `, ˜. The acute raises the voice, and the grave lowers it, while the circumflex is a kind of undulation of the voice between the two. It is seldom used among the moderns, except to show the omission of a letter, which makes the syllable long and open. Thus the French write *pâte* for *paste; tête* for *teste; fûmes* for *fusmes*, and the like. They formerly used the circumflex in the participles; some of their authors writing *conneu, peu,* others *connû, pû,* &c. The circumflex is not used in English.

CIRCUMGYRATION, the whirling motion of any body round a centre, as that of the planets round the sun.

CIRCUMLOCUTION, an ambages or circuitous mode of expression, used to express an idea either when a suitable term is not at hand, or to avoid the use of a single term either from delicacy or respect, or to soften the force of a direct expression.

CIRCUMPOLAR STARS, an appellation given to those stars which from their vicinity to the pole move round it without setting.

CIRCUMPOTATIO (*i.e.* a drinking around in succession), a universal custom at funerals among the nations of antiquity, including the Egyptians, the Greeks, and the Romans. Solon at Athens, and the decemviri at Rome, endeavoured to abolish this custom, thinking it indecorous that mirth and drunkenness should mingle with sorrow.

CIRCUMSCRIBED, in *Geometry*, a term applied to a figure which is drawn round another figure, so that all its sides or planes touch the inscribed figure.

CIRCUMVALLATION, or *Line of CIRCUMVALLATION*, in the art of war, a trench bordered with a parapet composed of the earth dug up from the ditch, and surrounding the camp of a besieging army. It is formed to guard the besiegers against any attempt of an enemy to relieve the place, and it also serves to prevent desertion.

CIRCUS, a place set apart for horse and chariot races among the Romans. The Greeks called such a place a hippodrome (ἱππόδρομος). At Rome, the circi were also used for popular meetings of various kinds, and are therefore described by the poets as localities in which friends and acquaintances who did not often meet had opportunities of seeing one another, and where persons might form new friendships. But the principal destination of a circus was, and remained to the latest times, horse and chariot races, together with other gymnastic and athletic exercises, which were designated by the name *ludi circenses*, or simply *circenses*, and of which the Romans were at all times passionately fond. These amusements of the circus did not materially differ from the Greek agones or contests, celebrated at Olympia, Delphi, and elsewhere; and were certainly of a nobler kind than the frightful gladiatorial fights of the amphitheatres, though sometimes a circus also was polluted by these inhuman exhibitions.

The most ancient, largest, and most celebrated circus at Rome was the *Circus Maximus*, in the valley between the Aventine and Palatine. Tradition assigns its construction to king Tarquinius Priscus, and it cannot have been older than the cloacæ, by which the ground was drained and made fit for buildings. It occupied the whole length of the valley, now called *La via de' Cerchi.* In the course of time this place was adorned in a variety of ways, and in the end it became one of the grandest and most magnificent structures of ancient Rome. At first the patricians and equites (for the plebeians were originally not admitted) viewed the games from temporary platforms (*spectacula, fori*, or *foruli*) which each had to make for himself; but afterwards a permanent building was constructed with regular tiers of seats all around the place, except on the side where the horses and chariots entered, and where in B.C. 329 stalls for horses and chariots (*carceres*) were erected. In B.C. 198 it was adorned with gilt statues; and other ornaments continued to be added until the time of Julius Cæsar, who made this circus about three stadia in length, and 400 feet in breadth. He further surrounded the whole of the inner area with a canal (*euripus*) 10 feet broad and as many feet deep. The podium and the lowest tier of seats were of stone, and the upper ones of wood. The circumference of the whole amounted to eight stadia; and the number of spectators said to have found room in this enormous structure is variously stated between 150,000 and 260,000. In the centre of the area was a low wall (*spina*) running lengthways down the course, and this spina was adorned by Augustus with a great obelisk. The same emperor also

built the *pulvinar* or emperor's seat. Claudius caused the carceres, which had been built of tufa and wood, to be made of marble. At each end of the spina there were three wooden pillars (*metæ*) of a conical shape, which were gilt by the emperor Claudius. The subsequent emperors likewise did much to enhance the magnificence of the circus; but it reached its height in the reign of Trajan, when, as Pliny observes, the long flanks of the circus rivalled the beauty of temples. This emperor enlarged the circus so much that it was capable of containing the whole Roman people; and we afterwards hear of 383,000 or even 485,000 spectators. Constantine brought to Rome the splendid obelisk which now stands before the north portico of the Lateran church, to adorn the Circus Maximus. This is the only remnant of the most ancient Roman race-course, although if excavations were made many valuable treasures of art would no doubt be discovered.

The circus next in importance at Rome was the *Circus Flaminius*. It was outside the city on the spot which had previously been called the *prata Flaminia*, where the plebeians used to meet for deliberation before the building of the circus, and where they, no doubt, celebrated the plebeian games. It is generally believed that this circus was built by Caius Flaminius, who was defeated by Hannibal, at the Thrasymene Lake, B.C. 217; at any rate we have no distinct allusion to it until the year B.C. 211. From the neighbouring temple of Apollo, it is sometimes called Circus Apollinaris. The traces of this circus, which can still be recognised, are somewhat more numerous than those of the Circus Maximus, although here, too, everything is built over; but the foundations of the church S. Caterina de' Funari, and of many other buildings in the neighbourhood, belong to the Circus Flaminius.

Besides these two, several other circi were built during the imperial period, as—1. The *Circus Agonalis*, in which only Greek games or contests (*agones*) were held, and the site of which can still be recognised on the Piazza Navona. It was built by the emperor Alexander Severus in the form of a Greek stadium. 2. The *Circus Vaticanus*, commenced by Caligula and completed by Nero. To it belonged the obelisk now standing on the area in front of St Peter's. A few remnants of its walls have been discovered, which show that it must have been destroyed at an early period. 3. The *Circus of Sallust*, situated in the gardens called the gardens of Sallust. It was constructed in such a manner that it could be used also for naumachiæ. Its site is still marked by considerable ruins. The obelisk belonging to it has been removed by Pope Pius VI. to the area in front of the Church della Trinita de' Monti. 4. The *Circus of Flora*, on the Quirinal hill, or between it and the Mons Pincius, is not often mentioned, and seems not to have been used for horse or chariot races. 5. The *Circus of Hadrian* is supposed to have been commenced by Nero, and to have been completed by Hadrian. It was situated in the garden of Domitia, an aunt of Nero, where Hadrian built his mausoleum, and was probably intended for funeral games in honour of those whose remains were deposited in the mausoleum. In the sixteenth and seventeenth centuries some interesting remains of this circus were discovered. 6. The *Circus of Caracalla* is to us the most important of all; for, though it was surpassed by others in splendour and magnitude, important remains of it still exist which give us an idea of the construction of such edifices in general. They are to be found outside the Porta S. Sebastiano, and still bear the name of "Il Circo," or "La Giostra di Caracalla." In all discussions upon ancient circuses, this one must be our guide, as it is more perfectly preserved than any other. It is very minutely described and figured in the work of Bianconi, *Descr. de' Cerchi, ed. Fea.*

All the circuses we have here noticed differed greatly in their length as well as in their breadth. Their original destination was often departed from; and especially the Circus Maximus, from its size, was often used as a place for hunting wild beasts, and for combats between whole troops of cavalry and infantry. It was on this account that Cæsar ordered the euripus to be made to protect the spectators in the lowest row against the infuriated beasts, and especially against the elephants. Besides this euripus, which Nero filled up again, the spectators in the lower seats were protected by iron railings. The most splendid part of the whole building was the spina, which was adorned with statues and altars, and in almost every case had an obelisk imported from Egypt.

As the Circensian games were so much enjoyed by the Romans, we may easily imagine that many other cities imitated them; and hence we find circi mentioned, at Azani, Anagnia, Alexandria in Egypt, Rhodes, Athens, Gaza, Jerusalem, and in Gaul at Nismes, Narbonne, and in the country of the Belgæ.

For a full description of the architectural detail of a circus, see the work of Bianconi above referred to, and Mr A. Rich in Smith's Dictionary of *Greek and Rom. Ant.*, article *Circus*. See also AMPHITHEATRE. (L. S.)

CIRENCESTER, or CICESTER, a parliamentary borough and market-town of England, county of Gloucester, and 16 miles S.E. of the town of that name; 88 miles by road, and 95 by the Great Western railway from London. It occupies the site of Corinum, Corinium, or Duro-cornovium, the capital of the Dobani and an important military station of the Romans, situated at the junction of three Roman roads. In 878 it was taken by the Danes; and was the seat of a great council held by Canute in 1020. A magnificent abbey for Black Canons, of which some remains still exist, was founded here in 1117 by Henry I. Numerous Roman remains have at various times been discovered here; and traces of the ancient walls, two miles in circuit, are still to be seen. It returns two members to parliament; and, not being incorporated, is governed by two high constables and 14 wardsmen, who are elected annually. Pop. (1851) 6096; electors (1851-2) 434. It stands on the river Churn, is connected by a branch with the Thames and Severn canal, and consists of four principal streets of generally well built houses, but is a place of no trade. The church is a fine old structure of the fifteenth century, with an embattled tower 134 feet high, a fine decorated porch, several lateral chapels, and many interesting monuments. It has a free grammar-school, three hospitals, alms-houses, savings-bank, museum, public library, dispensary, breweries, and a carpet factory. Market-days Monday and Friday. An agricultural college has been lately established in the vicinity, with chapel, lecture rooms, library, museum, laboratories, &c., and an experimental farm of 600 acres.

CIRRIPEDES. See index to MOLLUSCA.

CIRTA, a city of Numidia, in the country of the Massylii, situated on a steep rock, and nearly encircled by the Rummel, a tributary of the Ampsaga. It was regarded by the Romans as the strongest position in Numidia, and was made by them the converging point of all their great military roads in that country. By the early emperors it was allowed to fall into decay, but was afterwards restored by Constantine, from whom it took the name of Constantina, which it still retains.

CISNEROS, FRANCISCO XIMENES DE. See XIMENES.

CISALPINE (Latin *cis*, on this side, and *Alpes*), among the Romans was used to signify "on this side of the Alps," with respect to Rome—that is, to the south of the Alps, in opposition to *transalpine*, or beyond the Alps.

CISPADANA GALLIA, in *Ancient Geography*, a district of Italy, to the south of the Po, originally occupied, as its name imports, by the Gauls, and separated from Liguria on the W. by the Iria, running from S. to N. into the Po, and bounded on the S. by the Appenines, and on

the E. by the Adriatic. The term is formed analogically, frequent mention being made in Cicero, Tacitus, Suetonius, and ancient inscriptions, of the *Transpadani*, which, with *Cispadani*, are terms used with respect to Rome. Ptolemy calls the Cispadana *Gallia Togata:* it extended between the Po and Apennines to the Sapis and Rubicon.

CISSAMPELOS PAREIRA, a plant belonging to the natural order of *Menispermaceæ*, a native of South America and the West Indies, of which the root has been introduced into medicine as a diuretic, tonic, and aperient remedy; but the plant from which it is obtained in Brazil, whence it was first first brought to Europe, is still doubtful. It is called *Pareira brava*, or wild vine, and was extolled by the Brazilian practitioners not only as a remedy in diseases of the urinary organs, but as an antidote against the poison of serpents. Brodie has recommended its use in chronic urinary diseases, as in chronic irritations of the bladder; but many consider its virtues much over-rated both in this country and in Brazil.

CISTERCIANS, a religious order founded A.D. 1098, by St Robert, abbot of Molesme. It was so named from its original convent in the forest of Citeaux (Cistercium), about 14 miles N.E. of Beaune. This order became so powerful that it governed almost all Europe both in temporal and spiritual concerns; and through the exertions of St Bernard of Clairvaux had increased so rapidly in power, that within a century from its foundation it embraced 800 rich abbeys in different countries of Europe. Their rule was that of St Benedict. The Cistercians devoted themselves to a contemplative life, and practised great austerities. The abbeys of La Feité, Pontigny, Clairvaux, and Morimond, were offshoots of that of Citeaux; and produced in their turn a great number of separate communities, all which continued under the superintendence of the abbey of Citeaux. The abbey of Morimond alone possessed 700 benefices; and its supremacy was acknowledged by the military orders of Calatrava, Alcantara, and Montesa in Spain, and those of Christ and of Avis in Portugal. But the most famous of all the communities of this order was that of Clairvaux, founded by St Bernard. (See BERNARD, St). Towards the end of the twelfth century, however, the immense wealth of Citeaux began to operate unfavourably on its discipline, and led the way to great corruptions. Jean de la Barrière, abbot of Nôtre-Dame des Feuillants, near Toulouse, succeeded in 1577 in effecting a reform, which gave rise to the Feuillants in France; and likewise to the reformed Bernardines in Italy. But of all the reforms among the Cistercians, the most celebrated was that effected by the abbot of La Trappe in 1664.

Dependent on the abbey of Citeaux there were about 1800 monasteries and an equal number of nunneries. This ancient abbey was the burial-place of all the dukes of Burgoyne of the original line, with the exception of the first two, who died before its foundation. Citeaux has produced, besides St Bernard, two popes (or four according to some), and a great number of cardinals. The remains of this great abbey still exist.

The Cistercians were involved in the general fate of the religious orders during the period of the French revolution of 1789; and they were reduced to a few convents in Spain, Poland, the Austrian dominions, and the Saxon part of Upper Lusatia. Their habit is a white robe or cassock, with a black scapulary, and a woollen girdle. The nuns wear a white tunic and a black scapulary and girdle.—(Manriquez, *Annales Cistercienses*, 4 vols. folio, Lyons, 1642.)

CISTERN (Lat. *cisterna*), a reservoir, or receptacle for water; either natural or artificial.

CITADEL, a fortress or castle in or near a city, and intended for its defence.

CITADINESCA, a name given by some writers to the Florentine marble which appears to represent towns, palaces, ruins, rivers, &c.

CITHÆRON, a famous mountain, or rather a mountain range, in the south of Bœotia, separating that state from Megaris and Attica. It was very celebrated in Grecian mythology, and is frequently mentioned by the great poets of Greece, especially by Sophocles. It was on Cithæron that Actæon was changed into a stag, that Pentheus was torn to pieces by the Bacchantes whose orgies he had been watching, and that the infant Œdipus was exposed. This mountain, too, was the scene of the mystic rites of Bacchus; and the festival of the Dædala in honour of Juno was celebrated here.

CITHARA, a stringed musical instrument among the ancients, probably of the guitar kind. See LYRE.

CITIZEN, a native of a city, or a person who enjoys all the privileges and immunities of the city in which he resides, and of the state of which he is a member. In ancient Greece and Rome these privileges were so numerous and important as to be watched over with the most jealous care by those who enjoyed them. Among the Romans the rights of citizens were either public or private. The former class was technically called the *jus civitatis*, the latter the *jus Quiritium*. The first of these the Roman citizen enjoyed in his political, the second in his private and personal capacity.

The public rights of the Romans were the following:—1, The *jus census*, the privilege of being enrolled in the censor's books; 2, the *jus militiæ*, the right of serving in the army, in which originally none but citizens were allowed to enlist; 3, the *jus tributorum*, or right of paying the public *tributa* in contradistinction to the *vectigalia;* 4, the *jus suffragii*, the right of voting in the public assemblies of the people; 5, the *jus honorum*, the right of bearing public offices in the state; and 6, the *jus sacrorum*, the right of participating in the solemnities with which the public worship of the gods was celebrated. The private rights of the Roman citizens were seven in number:—1, *Jus libertatis*, the right of liberty, in virtue of which the Roman citizen could appeal to the people against the severity of magistrates, the cruelty of creditors, and the insolence of more powerful citizens; 2, the *jus gentilitatis et familiæ*, by which the privileges originally granted to a gens or family were secured to its later representatives; 3, the *jus connubii*, by which no Roman citizen was allowed to marry a slave, a barbarian, or a foreigner, unless by the express permission of the people; 4, the *jus patrium*, which gave a Roman father the complete power of life and death over his children; 5, the *jus dominii legitimi*, or the right of legal property; 6, the *jus testamenti et hæreditatis*, the right of making a will and succeeding to an inheritance; and 7, the *jus tutelæ*, the right of tutelage and wardship. Such were the rights of the Roman citizen in his political and social relations. As a nation the Romans were originally divided into *cives* and *peregrini*. Under the title of *peregrini* were included, until the time of Caracalla, the inhabitants of nearly all the Roman provinces; the citizens of foreign states on friendly terms with Rome; Romans who had lost their civitas; and freed men. Subsequently, a third class was introduced, the *Latini*, who enjoyed a modified civitas, and had the right of trade without that of marriage. Caracalla extended the civitas to every town and village that owned the dominion of Rome; but his generosity was confined to communities, and did not extend to individuals. When Justinian reformed the Roman code, he abolished altogether the gradation of classes. After his time there was no other division than that into subjects of the emperor and slaves.

CITRUS, a genus of plants belonging to the natural order of *Aurantiaceæ*, including the orange, the lemon, the lime, the shadock, &c. See BOTANY.

CITTA DI CASTELLO (the ancient *Tifernum Tiberinum*), a town of the Papal States, pleasantly situated on the left bank of the Tiber, delegation of Perugia, and 25 miles

N. by W. from the town of that name. It has a cathedral, many churches and convents, hospital, manufactures of silk twist, and some trade in wine and oil. Pop. 5430.

CITTA VECCHIA, a city of Malta. See MALTA.

CITTERN, an old species of guitar. In former times the cittern was a regular part of the furniture of a barber's shop; and it is frequently mentioned by our old dramatists.

CITY, according to Cowel, is a town corporate, which has a bishop and cathedral church, and is called *civitas*, *oppidum*, and *urbs*; *civitas*, because it is governed by justice and order of magistracy; *oppidum*, because it contains a great number of inhabitants; and *urbs*, because it is in due form surrounded with walls.

Kingdoms have been said to contain as many cities as they have sees of archbishops and bishops; but, according to Blount, *city* is a word that has obtained since the Conquest; for in the time of the Saxons there were no cities, but all the great towns were called burghs, and even London was then called *Londonburgh*, as the capital of Scotland is called *Edinburgh*. Even long after the Conquest the word *city* was used promiscuously with *burgh*, as in the charter of Leicester, where it is called both *civitas* and *burgus*; which shows that those writers were mistaken who tell us that every city was or is a bishop's see, though with us the word city usually signifies such a town corporate as has a bishop and a cathedral church.

As to the ancient state of cities and villages, whilst the feudal policy prevailed they held of some great lord, on whom they depended for protection, and were subject to his arbitrary jurisdiction. The inhabitants were deprived of the natural and most unalienable rights of humanity. They could not dispose of the effects which their own industry had acquired, either by a latter will or by any deed executed during their life. They had no right to appoint guardians for their children during their minority. They were not permitted to marry without purchasing the consent of the lord on whom they depended. If once they had commenced a lawsuit, they dared not terminate it by an accommodation, because that would have deprived the lord, in whose court they pleaded, of the perquisites due to him on giving his judgment. Services of various kinds, no less disgraceful than oppressive, were exacted from them without mercy or moderation. The spirit of industry was checked in some cities by absurd regulations, and in others by unreasonable exactions; nor would the narrow and oppressive maxims of a military aristocracy have permitted it ever to rise to any degree of vigour or independence.

The freedom of cities was first established in Italy, owing principally to the introduction of commerce. As soon as they began to turn their attention towards this object, they became impatient to shake off the yoke of their insolent lords, and to establish among themselves a free and equal government. The German emperors, especially those of the Franconian and Suabian lines, as the seat of their government was far distant from Italy, possessed a feeble and imperfect jurisdiction in that country. Their perpetual quarrels, either with the popes or their own turbulent vassals, diverted their attention from the interior policy of Italy, and gave constant employment for their arms. These circumstances induced some of the Italian cities towards the beginning of the eleventh century to assume new privileges, to unite together more closely, and to form themselves into bodies politic, under the government of laws established by common consent. The rights which many cities acquired by bold or fortunate usurpations, others purchased from the emperors, who deemed themselves gainers when they received large sums for immunities which they were no longer able to withhold; and some cities obtained them gratuitously, from the facility or generosity of the princes on whom they depended. The great increase of wealth which the crusades brought into Italy occasioned a new kind of fermentation and activity in the minds of the people, and excited such a general passion for liberty and independence, that before the conclusion of the last crusade, all the considerable cities in that country had either purchased or extorted large immunities from the emperors.

This innovation was not long known in Italy before it made its way into France. Louis le Gros, in order to create some power that might counterbalance those potent vassals who controlled or gave law to the crown, first adopted the plan of conferring new privileges on the towns within his own domain. These privileges were called *charters of community*, by which the inhabitants were enfranchised, all marks of servitude abolished, and corporations or bodies politic were formed, to be governed by a council and magistrates of their own nomination. These magistrates had the right of administering justice within their own precincts, of levying taxes, and of embodying and training to arms the militia of the town, which took the field when required by the sovereign, under the command of officers appointed by the community. The great barons imitated the example of their monarch, and granted similar immunities to the towns within their territories. They had wasted such great sums in their expeditions to the Holy Land, that they were eager to lay hold on this new expedient for raising money by the sale of those charters of liberty. Though the constitution of communities was as repugnant to their maxims of policy as it was adverse to their power, they disregarded remote consequences in order to obtain present relief. In less than two centuries servitude was abolished in most of the cities of France, which consequently became free corporations. Much about the same period the great cities of Germany began to acquire like immunities, and laid the foundations of their present liberty and independence. The practice spread quickly over Europe, and was adopted in Spain, England, Scotland, and all the other feudal kingdoms.

The Spanish historians are almost entirely silent concerning the origin and progress of communities in that kingdom; so that it is impossible to fix, with any degree of certainty, the time and manner of their first introduction there. It appears from Mariana (whose credulity, however, has frequently impaired the authority of his narrative), that in the year 1350 eighteen cities had obtained a seat in the cortes of Castile. In Aragon cities seem early to have acquired extensive immunities, together with a share in the legislature. In the year 1118 the citizens of Saragossa had not only obtained political liberty, but were declared to be of equal rank with the nobles of the second class; and many other immunities, unknown to persons in their rank of life in other parts of Europe, were conferred upon them. In England, the establishment of communities or corporations was posterior to the Conquest. The practice was borrowed from France, and the privileges granted by the crown were perfectly similar to those above enumerated. It is not improbable that some of the towns in England were formed into corporations under the Saxon kings; and that the charters granted by the kings of the Norman race were not charters of enfranchisement from a state of slavery, but a confirmation of privileges which they had already enjoyed. The English cities, however, were very considerable in the twelfth century. Fitz-Stephen, who lived in the time of Henry II., gives a description of the city of London; and the terms in which he speaks of its trade, its wealth, and the number of its inhabitants, would suggest no adequate idea of its present state. But all ideas of grandeur and magnificence are merely comparative. It appears from Peter of Blois, archdeacon of London, who flourished in the same reign and had good opportunity of being informed, that this city, of which Fitz-Stephen gives such a pompous account, contained but 40,000 inhabitants. The other cities were small in proportion, and in no condition to extort any ex-

tensive privileges. That the constitution of the burghs of Scotland in many circumstances resembled that of the towns of France and England, is manifest from the *Leges Burgorum* annexed to the *Regiam Majestatem.*

CIUDAD RODRIGO, a town on the Agueda, province of Salamanca, Spain. It is fortified, and has some good public buildings, including a cathedral (built A.D. 1190), several churches and convents, an arena for bull-fights, &c. In the principal square are three Roman columns brought from the ancient Malabriga. A bridge connects the city with the suburbs, which are surrounded by well cultivated and fertile plains. The town, otherwise uninteresting, has been rendered famous by the sieges it underwent during the Peninsular war. It was taken by Marshal Massena in 1810, and again by the Duke of Wellington in 1812. Pop. 4500.

CIUDAD REAL, capital of the province of Ciudad Real, Spain; 97 miles S. from Madrid, on a plain between the Jabalon and Guadiana. It was built and fortified by Alonso el Sabio in 1264, to check the progress of the Moors; and portions of the walls and towers remain. It has several fine churches, and a large hospital, founded by Cardinal Lorenzana. It is one of the least commercial capitals of Spain, deriving most of its trade from agriculture and an annual fair. Pop. 10,000.

CIUDAD REAL, or CIUDAD DE LAS CASAS, a city of Mexico, capital of the State of Chiapas, is situated in the plain of Gueizacattan, about 430 miles S.E. of Mexico. It has a cathedral, four convents for monks and one for nuns, two chapels, hospital, and about 6000 inhabitants.

CIUDADELA, a city, formerly the capital of the island of Minorca, at the head of a deep and narrow bay on its W. coast, 25 miles N.W. of Mahon. It is surrounded by walls, and has a fine Gothic church. Pop. about 5000.

CIVET, a kind of perfume approaching in smell to musk and ambergris. It is obtained from two species of the genus Viverra, one of which is found in Africa and the other in Asia. The civet is contained in a sac situated beneath the tail of both the male and female; and by a contractile movement of the animal it is made to issue through an aperture in the sac. It has the consistence of honey, a clear yellowish colour, and an odour that is disagreeably powerful till diluted by mixture with some other substance. This animal, popularly known as the civet-cat, is of a cinereous hue, tinged with yellow, and marked with dusky spots. (See index to MAMMALIA.) Civets are reared with care for the sake of this secretion, especially in Abyssinia. Civet, when genuine, is worth from 30s. to 40s. an ounce.

CIVIC CROWN, *Corona Civica*, a garland of oak leaves given by the ancient Romans to the soldier who had saved the life of a citizen in battle. The civic crown was accounted the next in honour to the *Corona Obsidionalis*, or that presented by a beleaguered army to the general who had effected their liberation. Plutarch, in his life of Coriolanus, accounts for the preference given to the oak as the material for civic crowns; namely, that the oak was sacred to Jupiter, the guardian of the city. Pliny, in speaking of the honour and privileges conferred on him who had merited this crown, observes, that he who had once obtained it might wear it always. When he appeared at the public spectacles, the senate and people rose up; and on these occasions a place next the senate was reserved for him. He was freed from all public burdens, as were also his father and his grandfather by the father's side. He was also to be regarded in the light of a parent by the person whose life he had preserved.

CIVIDADE, a city of northern Italy, government of Venice and delegation of Udine, on the river Natisone, over which there is a bridge 250 feet in length. It has a collegiate church with a library and archives, and a museum. Pop. 6000.

CIVIL (Lat. *civilis*, from *civis* a citizen), in a general sense, relating to the community, or to the policy and government of the citizens and subjects of a state; as in the phrases civil government, civil right, civil war.

CIVIL, in a popular sense, is applied to a complaisant and polite behaviour in the ordinary intercourse of life.

CIVIL has also several other significations, its meaning in each case implying contrariety to that with which it is used; as civil and criminal, civil and ecclesiastical, civil and military. (See also CIVIL STATE, and CIVIL YEAR.)

CIVIL *Death*, anything that cuts off a man from civil society, or its rights and benefits; as condemnation to the galleys, or to death, to perpetual banishment, outlawry, excommunication, entering into a monastery, &c.

CIVIL LAW

Is a term applied by way of eminence to the municipal law of the Romans. This system of jurisprudence has for many ages been regarded as one of the most conspicuous monuments of human wisdom and genius; and its powerful influence on modern legislation has been felt and acknowledged by every civilized nation of Europe. Although it has long ceased to retain the full authority of written law, it can never cease to attract the attention, and to excite the admiration, of lawyers who are capable of ascending to this clear and copious fountain of juridical knowledge. The study of the civil law may formerly have engrossed a larger share of notice than it can justly claim; but there are many reasons for supposing that, in this country at least, it is too much neglected, both by professional lawyers, and by those who aspire at the reputation of general learning.

It is stated by Mr Hallam, that "the stream of literature that has so remarkably altered its channel within the last century, has left no region more deserted than those of the civil and canon law. Except among the immediate disciples of the papal court, or perhaps in Spain, no man, I suppose, throughout Europe will ever again undertake the study of the one; and the new legal systems, which the moral and political revolutions of this age have produced, and are likely to diffuse, will leave little influence or importance to the other."[1] But in all Catholic countries, the canon law is a necessary study; and even the Protestants of Germany think it a study which cannot be safely neglected. When to a certain extent we recommend the study of the canon as well as the civil law, we at the same time make a clear distinction between the utility to be derived from the one and from the other. A familiar acquaintance with the civil law we are disposed to regard as the best foundation of all juridical science: the student, duly initiated in classical learning, may thus acquire a concise and elegant mode of reasoning on the multifarious topics of jurisprudence; and he thus becomes familiar with those maxims of law which have extended their influence to all the civilized portions of Europe. This species of knowledge is therefore highly valuable in

[1] Hallam's View of the Middle Ages, vol. iii. p. 519.

itself, and it guides us to other knowledge, of more immediate application to the ordinary business of life. In several countries, the civil law continues to be studied with a degree of ardour which Mr Hallam could not fail to consider as surprising, and perhaps preposterous. But the canon law cannot claim the same pre-eminence, nor is it to be recommended to students on account of its intrinsic excellence: it is to be considered as the spurious offspring of the civil law, and as having gradually attained its full growth under the fostering care of priestly usurpation; what is most valuable, it has derived from the Roman jurisprudence, and its own peculiar maxims have all the same general tendency towards the power and aggrandizement of the church.

In those countries most remarkable for the extent and solidity of their erudition, namely, in Germany and Holland, the study of the civil law has long constituted an essential branch of a liberal education; and they persuade themselves that many advantages result from such a plan of study. Many of their professed scholars are excellent civilians, and many of their professed civilians are excellent scholars. It is sufficiently obvious that those who are acquainted with the phraseology and with the spirit of the Roman law, will readily understand many passages of the Latin classics which to others must remain obscure and unintelligible. Even the poets admit of such illustration: Plautus, Horace, and Ovid may frequently be explained from the writings of the civilians.[1]

These general assertions will best be confirmed by a particular example; and the examples are so abundant that the chief difficulty lies in the necessity of making a selection. The subsequent passage in one of the epistles of Pliny may however be regarded as sufficient for our purpose. "Tu quidem pro cætera tua diligentia admones me, codicillos Aciliani, qui me ex parte instituit heredem, pro non scriptis habendos, quia non sint confirmati testamento: quod jus ne mihi quidem ignotum est, quum sit iis etiam notum qui nihil aliud sciunt. Sed ego propriam quandam legem mihi dixi, ut defunctorum voluntates, etiamsi jure deficerent, quasi perfectas tuerer. Constat autem, codicillos istos Aciliani manu scriptos. Licet ergo non sint confirmati testamento, a me tamen, ut confirmati, observabuntur."[2] This point of law, says Pliny, is even known to those who are ignorant of every other; but it seems nevertheless to have been completely misapprehended by Dr Adam, who has thus stated the doctrine of codicils: "When additions were made to a will, they were called *codicilli*. They were expressed in the form of a letter addressed to the heirs, sometimes also to trustees (ad fideicommissarios). It behoved them however to be confirmed by the testament. Plin. *Ep*. ii. 16."[3] The first of these sentences contains a definition of a modern codicil; but, according to the civil law, a codicil was a less solemn form of a will. It might be made by a person who was either testate or intestate; in other words, it could either accompany or subsist without a testament. A person might leave several codicils; whereas no *pagan*, that is, no person who was not a soldier, could leave more testaments than one. It was essential to the character of a testament that it should institute an heir; but a codicil was in all cases incompetent for that purpose, and could only bequeath legacies and trusts: it therefore could not disinherit one heir, or substitute another. As the law stood in the age of Caius, a legacy bequeathed by a codicil, and not ratified by a testament, was null and void,[4] and, according to the doctrine which, in more general terms, was afterwards stated by Papinian, where the codicil was of a date prior to the will, it was held to be ineffectual unless confirmed by that will, or by another codicil.[5] The notion of Dr Adam, that a codicil must succeed a testament, and that it must nevertheless be confirmed by a testament, cannot very easily be comprehended; but the statement of the ancient writer, when properly understood, is easily reconciled to the doctrine of the civilians. The individual whom he mentions had first made a codicil, and afterwards a testament, and had neglected to confirm in the one a legacy which had been bequeathed in the other: a direct bequest could not be effectually made in this manner, but Pliny expresses his determination to take no advantage of the legal informality.

The legislation of Rome under the regal dynasty must have been extremely simple. Of this era however very few reliques have been preserved, nor are the genuine sufficiently distinguished from the spurious. The *Leges Regiæ* have been collected by Lipsius,[6] and other men of learning; and of the supposed laws of Romulus a separate collection was published by Balduinus.[7]

After the expulsion of the last king, the want of a regular code of laws appears to have been felt by the Romans, who were yet an inconsiderable and a rude people. According to the uniform testimony of their own writers, they had recourse to the expedient of sending a deputation to Greece, in order to procure information respecting the laws of a kindred nation. The commonly received account of this embassy was called in question by Giambattista Vico,[8] a professor of rhetoric, who ought to have been a professor of law, at Naples: he has been followed by Bonamy,[9] Gibbon, Niebuhr, Wachsmuth, and many other writers, both civilians and historians. The current of opinion in Germany is decidedly in favour of his conclusion, which however we are not yet fully prepared to admit.[10]

It is stated by Livy, and by Dionysius of Halicarnassus, that ambassadors were sent to Greece, in order to collect information respecting the laws of that country; and the same account, or nearly the same, is repeated by many other ancient writers. Angelo Mai, adopting the opinion of Vico, has urged as an objection against this account, that it is

---

[10] On the subject of this controversy, two articles, written by Berriat St. Prix, may be found in that valuable repository the *Thémis, ou Bibliothèque du Jurisconsulte*, tom. iv. p. 304. tom. vi. p. 269.

nowhere mentioned in the writings of Cicero:[1] but if we were to admit the fact, it would not be necessary to admit the inference; for Cicero might or might not find occasion to refer to an event which, so far as we can discover, no person regarded as doubtful. The following expressions however seem to contain a manifest allusion to the influence of the Athenian upon the Roman laws: "Adsunt Athenienses, unde humanitas, doctrina, religio, fruges, jura, leges ortæ, atque in omnes terras distributæ putantur."[2] This passage occurs in one of his orations; and, in another work, Cicero notices the coincidence or identity of certain decemviral laws with those of Solon.[3] In the subsequent passage, Tacitus evidently alludes to a fact which must have been considered as incontrovertible: "Creatique decemviri, et accitis quæ usquam egregia, compositæ duodecim Tabulæ, finis æqui juris."[4] The younger Pliny thus addresses one of his friends: "Habe ante oculos, hanc esse terram quæ nobis miserit jura, quæ leges non victa acceperit, sed petentibus dederit; Athenas esse, quas adeas; Lacedæmonem esse, quam regas."[5] Pomponius has likewise adopted the same account: "Postea, ne diutius hoc fieret, placuit publica auctoritate decem constitui viros, per quos peterentur leges a Græcis civitatibus, et civitas fundaretur legibus."[6] Many other passages of ancient writers might be accumulated, not to strengthen the original authority on which we find the fact stated, but to evince that this fact was generally, if not universally admitted.

Dr Macieiowski, professor of the civil law in the university of Warsaw, has directed the edge of his criticism against the character of Livy and Dionysius as historians;[7] and we are not unwilling to admit that on this subject his opinion is entitled to attention. The value and importance of Dionysius's work for the early history of the Roman law, has been discussed by Dr Schulin;[8] and with respect to the character of Livy, we only think it necessary to remark that we regard him as no incompetent authority for such a fact as he has recorded. Had the fact of such a mission been very absurd or very incredible in itself, the state of the question would have been essentially different. It is further urged by the same learned professor, that all the ancient monuments of Roman history must have perished when the city was burnt by the Gauls. But it is not to be doubted that the laws of the twelve Tables, or at least ample portions of them, survived the destruction of the city: those laws are repeatedly mentioned by Cicero, as we should now mention the Great Charter, not as what has existed, but as what still exists;[9] at a later period they were the subject of various commentaries, nor do we meet with any hint or suggestion that such commentaries related to fragments, instead of the entire collection. It is indeed stated by Livy that, after this calamity, an attempt was made by public authority to recover the regal and decemviral laws;[10] and we learn from Cyprian that, during the third century, the laws of the twelve Tables were still to be found engraved on tablets of brass.[11] If then the laws themselves were rescued from the ruins of the city, is there any difficulty in imagining, or any absurdity in believing, that their genuine history was likewise preserved? Let us even suppose that every written monument perished in the common wreck; yet the nation itself was not exterminated; and the oral tradition of one generation became the lettered record of the next.

Some writers have involved the subject in unnecessary doubt and difficulty, by misapprehending the real state of the question; for it has been seriously asked whether the decemvirs transferred the entire laws of Solon to the twelve Tables. If any person imagines that they transferred the entire laws of Solon, or any other legislator, he manifestly entertains a very crude opinion; and he who opposes such an opinion, can only be thought to combat a phantom. Let us examine the passage of Livy as our original text: "Quum de legibus conveniret, de latore tantum discreparet, missi legati Athenas Sp. Postumius Albus, A. Manlius, Ser. Sulpicius Camerinus; jussique inclytas leges Solonis describere, et aliarum Græciæ civitatum instituta, mores, juraque noscere."[12] He soon afterwards states that those ambassadors were nominated among the decemvirs for two reasons: "His proximi legati tres habiti, qui Athenas ierant; simul ut pro legatione tam longinqua præmio esset honos; simul peritos legum peregrinarum ad condenda nova jura usui fore credebant." Nothing can be more plain and intelligible than this account. Three ambassadors, or as we might with equal propriety describe them, three messengers, were sent to Greece, with instructions to procure a copy of the laws of Solon, and to acquaint themselves with the laws and institutions of other states of Greece besides Athens. In the commission for preparing a body of laws, these three individuals were included, in order that this honour might compensate them for their former labours, and that the knowledge which they had acquired of foreign jurisprudence might be rendered useful in the compilation of a new body of laws. The expression *ad condenda nova jura* certainly does not suggest the idea of transferring laws already made. If therefore any enquirer should succeed in proving, what it will however be very difficult to prove, that there is not a single coincidence between any existing fragment of the twelve Tables, and any existing fragment of the laws of Athens or any other state of Greece, no argument could thence be deduced

against Livy's account of the mission. The Romans, at that period a rude and simple nation, were anxious to obtain some knowledge of the laws, customs, and institutions of a kindred people, before they attempted to reduce their own laws to something approaching to a systematic form; and in order to procure this knowledge, they adopted an expedient which must strike every person, who reflects on the state of society at that remote era, as the most obvious and practicable that could have been devised. But of the new laws with which they thus became acquainted, it is evident that many were utterly to be rejected, some to be abhorred; and they might learn what to avoid, as well as what to imitate. We might as rationally expect one nation to adopt the entire language as the entire laws of another nation. When the decemvirs were employed in their important task, the city of Rome had seen three centuries of years, and during that period had partly been governed by written, and partly by unwritten laws. It is therefore to be supposed that the twelve Tables chiefly consisted of a digest of what was regarded as the best portion of their municipal enactments and customs: customary law, which acquires its vigour and consistency in the early stages of society, was doubtless a very essential part; and some modifications, perhaps various regulations entirely new, might be derived from a foreign source. This we conceive to be the authentic history, and these the genuine effects, of the famous mission into Greece; and in the general texture of this story we find nothing that exceeds the limits of rational belief.

Dr Dunbar has well remarked that "the Romans, while yet a rude people, disdained not to appoint an embassy to enquire into the jurisprudence of the Greeks, and to supply, from that fountain, the deficiencies in their civil code. This embassy seems to have been suggested by Hermodorus, an exiled citizen of Ephesus, who afterwards eminently assisted in interpreting the collection of laws brought from Greece. His public services met with a public reward. A statue was erected to him in the Comitia at the public expense; an honour which the jealousy of Rome would have denied to a stranger in a less generous age. But, at this period, she acted from a nobler impulse; and the statue erected to Hermodorus was erected, in reality, to her own honour. Yet the name of this Ephesian, which casts a lustre upon Rome, seemed to cast a shade upon his native city; and that people, according to Heraclitus, deserved to have been extirpated to a man, who had condemned such a citizen to exile."[1] This agency of Hermodorus is not mentioned by Livy: but the erection of his statue is recorded by the elder Pliny;[2] and his connexion with the decemvirs is likewise stated by Pomponius: "Et ita ex accidentia appellatæ sunt Leges duodecim Tabularum: quarum ferendarum auctorem fuisse decemviris Hermodorum quendam Ephesium, exulantem in Italia, quidam retulerunt."[3] By the word *auctor*, as used in this passage, we are evidently to understand a person who advised or influenced the decemvirs; and according to Pliny, his services were those of a translator or expounder. It is therefore highly probable that he was chiefly employed in expounding to them the Greek laws, of which they had obtained a transcript. As he appears to have been a person of superior talents,[4] his own comments might be useful and important; but we are by no means inclined to estimate his services so highly as Professor Gratama, who represents him as the real author of the laws of the twelve Tables.[5]

Before we dismiss the history of the twelve Tables, we are tempted to notice an opinion which another modern author has delivered respecting one of their enactments. "Ancient histories," says Lord Kames, "are full of incredible facts that passed current during the infancy of reason, which at present would be rejected with contempt. Every one who is conversant in the history of ancient nations, can recal instances without end. Does any person believe at present, though gravely reported by historians, that in old Rome there was a law for cutting into pieces the body of a bankrupt, and distributing the parts among his creditors?"[6] This is the speculation of an ingenious man, who is sometimes too precipitate in his conclusions. Annæus Robertus[7] and Heraldus[8] have each proposed a mitigating interpretation of this law of the twelve Tables: Bynkershoek was solicitous to prove that the creditors were entitled to divide, not the body, but the price of the insolvent debtor;[9] and his opinion has been adopted by the learned Dr Taylor,[10] and by some other civilians. But this opinion can neither be reconciled with the obvious meaning of the words, nor with the ancient mode of understanding them.[11] Those who consider such an enactment as altogether incredible, ought at the same time to consider the real character of the Roman people at that period of their history. They certainly were not distinguished by the gentler virtues; and if their laws were altogether silent as to the treatment of debtors, we ascertain from other sources of information that it was extremely harsh and cruel. In more rude communities, where commerce is almost entirely unknown, and where the poor are completely subjected to the rich, the insolvent debtor is very apt to be treated as a criminal. In ancient Rome, we know from historical records, not merely from the letter of the law, that he might be reduced to the condition of a slave; and it is obvious to every person acquainted with ancient history, that the unrelenting treatment of debtors was a ground of open dissension between the different orders of the people. The same laws which conferred on the father of a family the power of life and death over his wife and children, and which awarded capital punishment against the author of a satirical poem, may without much difficulty be conceived to have disposed of a poor debtor's person in the most summary manner.

It was in the 302d year from the building of the city that the decemvirs were appointed, and were invested with extraordinary powers, for the purpose of compiling a body of laws. They accordingly completed ten tables, which in the following year were confirmed by the comitia centuriata; but as some deficiencies were still to be supplied, decemvirs were again created, and the labour was thus brought to a conclusion. The laws of the twelve

[11] Dr Valpy, a learned divine, has confuted the opinion of Bynkershoek and Taylor, in a long note subjoined to his *Sermons preached on public Occasions*, vol. ii. p. 1. Lond. 1811, 2 vols. 8vo.

Tables were illustrated by the commentaries of several ancient lawyers, and among the rest by Antistius Labeo and Caius: the fragments of those laws have been collected and explained by many of the moderns, by Balduinus, Rævardus, Marcilius, Augustinus, Gravina, Funccius, Bouchaud, and others;[1] but the most able and conspicuous labourer in this province is the younger Gothofredus, whose edition of the Theodosian Code has rendered his name illustrious in the history of jurisprudence.[2]

Law assumed the form of a science during the latter ages of the republic; and jurisprudence, like philosophy, was at length subdivided into sects.[3] The chief splendour of the Roman lawyers is to be traced from the reign of Augustus to that of Alexander Severus;[4] and the last name of great celebrity is that of Herennius Modestinus.[5] With this pupil of Ulpian, the oracles of the civilians became mute:[6] the succeeding lawyers are only known as compilers or expounders; and although the law was long afterwards taught at Rome, Constantinople, and Berytus, we cannot in those declining annals discover any vestiges of ancient genius. The reign of Constantine was not conspicuous for legal science; and by fixing the seat of empire at Byzantium, he diminished all the chances or probabilities of improvement. To the great body of those who inhabited the new metropolis, the language of the law was a foreign language; nor was this the only circumstance unfavourable to the cultivation and progress of jurisprudence.

It is well known that the decisions of certain lawyers obtained the force of law.[7] In a rescript of Constantine, dated in the year 327, we find the highest authority ascribed to the opinions of Julius Paulus,[8] who flourished at the close of the second and the commencement of the third century. After an interval of nearly one hundred years, appeared another imperial constitution, intended to regulate the number and weight of legal opinions. In the judges themselves very little confidence seems to be reposed, nor is it difficult to imagine that their general merits are not undervalued: they are bound to decide points of law, according to the number of accredited opinions; when the numbers are equal, and the decision of Papinian can be produced on one side of a question, his authority must be allowed to preponderate, "qui, ut singulos vincit, ita cedit duobus;" and it is only in the case of a perfect equilibrium of legal opinions, that they are left to the full exercise of their own discrimination.[9] This arrangement is so entirely mechanical, that it is manifestly adapted to the lowest standard of attainment in those entrusted with the administration of the law.

Of the writings of the ancient lawyers, innumerable fragments are incorporated in the Pandects, and various others have been collected by Schulting. The recent discovery of several reliques of the Roman law has given a fresh impulse to the continental civilians. New portions of the Theodosian Code have been brought to light by Clossius and Peyron. To the Vatican Fragments, published by Angelo Mai,[10] we can only make a transient allusion; but the recovery of the long-lost Institutes of Caius is too remarkable an event to be noticed in the same manner. An unsatisfactory abridgement of these Institutes had long been known; but the genuine text of Caius was not discovered till the year 1816. In the library of the chapter of Verona, the celebrated Niebuhr, author of the Roman history, found a juridical manuscript of great antiquity; and when a short extract was communicated to Savigny, he easily ascertained that it formed a portion of the original work of this ancient lawyer, who flourished about the age of Antoninus. In the course of the following year, the Royal Academy of Berlin dispatched to Verona two distinguished members of the university, Professor Göschen, a civilian, and Professor Bekker, a philologer, entrusted with the important commission of executing a transcript of the manuscript; and in the performance of this very formidable task, they were greatly aided by the spontaneous and indefatigable services of Dr Bethmann Holweg, who was afterwards appointed a professor of law at Berlin. The manuscript is a *codex rescriptus*, and to a considerable extent *bis rescriptus;* nor is it easy to conceive the difficulty of deciphering an ancient relique in this condition. Without the aid of a chemical process, it would have been impossible to succeed in the attempt to read what had thus been written and erased.[11] According to the opinion of Kopp, the learned author of the *Palæographia Critica*, who is allowed to possess great knowledge of ancient monuments, the manuscript must have been written before Justinian's reformation of the law.[12] After much laborious preparation, the Institutes of Caius or Gaius were published in the most able and satisfactory manner by Professor Göschen,[13] who, since that period, has been removed to the university of Göttingen, where he now lectures to numerous auditories. He published a second edition in 1824, and several other editions have already appeared. Although the manuscript has been exposed to frequent and material mutila-

5 The fragments of Modestinus have been illustrated by many different civilians, and, among others, by Brenkman, in a work entitled "De Eurematicis Diatriba: sive, in Herennii Modestini librum singularem Περὶ Εὑρηματικῶν Commentarius." Lugd. Bat. 1706, 8vo. See Bachii *Historia Jurisprudentiæ Romanæ*, p 506. edit. Stockmann. Lipsiæ, 1807, 8vo.

6 "Atque hic jurisconsultorum finis est, hic oracula jurisconsultorum obmutuere; sic ut ultimum jurisconsultorum Modestinum dicere liceat, cessim et retro collapsa jam jurisprudentia." (Gothofredi Hist. Juris Civilis, p. 14.)

7 "Responsa prudentium sunt sententiæ et opiniones eorum, quibus permissum est jura condere: quorum omnium si in unum sententiæ concurrant, id quod ita sentiunt, legis vicem obtinet; si vero dissentiunt, judici licet, quam velit sententiam sequi; idque rescripto divi Hadriani significatur." (Caii Institutiones, lib. i. § 7.) This is one of the numerous instances in which the Institutes of Caius reflect a strong light on the history of the Roman law. Before their discovery, this rescript of Hadrian was totally unknown to modern civilians.

tions, much remains to instruct and to interest the learned enquirer; and the book has accordingly been received by the foreign civilians with a degree of ardour and exultation, not easily conceived by those who are unacquainted with the progress of such studies among some of the continental nations. Its value in elucidating the history of the Roman law has been discussed by Schrader.[1] Caius has already been illustrated in many other publications, and, in some of the German universities, has been illustrated in separate courses of lectures. It may safely be affirmed, that the discovery of the Institutes of Caius forms a new era in the history of jurisprudence.

Before we proceed to mention the legislative labours of Theodosius, it will be proper to state that, in the compilation of a code of laws, he had been preceded by two private lawyers, Gregorius or Gregorianus, and Hermogenes or Hermogenianus, for their respective names are not completely ascertained.[2] From the order in which their codes are mentioned by ancient writers, it is to be inferred that the labours of Gregorius preceded those of Hermogenianus. Some fragments of both codes have been preserved by Anianus.[3] Gregorius appears to have collected the imperial constitutions belonging to the intermediate reigns, from Hadrian to Constantine the Great. Hermogenianus is supposed to have formed a supplementary collection; and the remaining fragments consist entirely of the constitutions of Dioclesian and Maximinian. Of the former of these compilers, the personal history is involved in complete obscurity. According to the conjectures of modern civilians, the latter must have flourished in the reign of Constantine; and he is supposed to be the same Hermogenianus whose works are quoted in the Pandects. Both compilations are apparently to be considered as the undertakings of private individuals: the ancient commentator on the Theodosian Code has indeed averred that their authority is confirmed by a law, "sub titulo de Constitutionibus Principum et Edictis,"[4] and Gothofredus has naturally enough relied on this averment; but the commentator probably alluded to a constitution which has recently been discovered, and which certainly affords no adequate support to such an opinion. The emperor merely declares his resolution of forming a collection of imperial constitutions, "ad similitudinem Gregoriani atque Hermogeniani Codicis:" he thus acknowledges the propriety of such a model, but is silent with respect to any public sanction of those antecedent codes.[5] It is however probable that they obtained some degree of authority in the forum.[6] This circumstance may naturally be imputed to the intrinsic value of such a collection of laws; and we may conceive the two codes to have obtained the same degree of authority as might belong to the publication of an English author, who had prepared a digest or an abridgement of the Statutes. In either case the credit of the compiler must depend, not upon any formal sanction, but upon the fidelity with which he is generally believed to have executed his undertaking.

It appears to have been the original intention of Theodosius to compile two codes, arranged according to different plans; but his second code was never completed, nor is it easy to conjecture what specific plan he had contemplated. The emperor had thus divulged his intention in the year 429, and the Theodosian Code received his sanction on the fifteenth of February 438. This code of laws, which is sometimes erroneously ascribed to Theodosius the Great, derived its origin from his grandson Theodosius the younger. On the decease of the first Theodosius, the Roman empire was divided between his two sons, the provinces of the east being allotted to Arcadius, those of the west to Honorius. From the sovereign of the east descended Theodosius the Second: after the death of his father and of his uncle, he again united the dominions which had thus been partitioned; but conferring the titles of Cæsar and Augustus upon Valentinian the Third, who married his daughter Licinia Eudoxia, he assigned to him the western provinces of the empire. This son-in-law, who became his successor at Constantinople, was likewise his cousin, being the son of Constantius Cæsar, and of Galla Placidia, the daughter of Theodosius the Great.

The compilers of the code were eight in number, and, as Gothofredus has remarked, they all occupied stations which required an acquaintance with the laws. Antiochus, who was placed at their head, has been confounded by him, as well as by Heineccius, with Antiochus the eunuch, and likewise with a third individual of the same name.[7] By a constitution, which has lately been discovered, and which bears the date of 435, the emperor had invested these commissioners with power to retrench what was superfluous, to add what was wanting, to change what was ambiguous, and to correct what was incongruous.[8] Justinian afterwards invested his commissioners with more ample powers: they were even authorized to consolidate several constitutions into one; and we may presume that neither of the two codes exhibited the imperial laws, or at least a large proportion of them, in their original state. In the novel which sanctions the Theodosian Code, the emperor evidently admits that the compilers whom he had employed were not mere copyists: "Manet igitur, manebitque perpetuo, elimata gloria conditorum, nec in nostrum titulum demigravit nisi lux sola brevitatis."

This code contains the edicts and rescripts of sixteen emperors; and its chronology extends from 312 to 438, thus embracing a period of 126 years. It commences with the reign of the first Christian emperor, and there is a systematic exclusion of the constitutions issued by the military adventurers who, during that interval, were finally unsuccessful in their attempts to usurp the government; but the selection is not limited to the constitutions of the Christian princes, for here we find the apostate Julian among other imperial lawgivers. The code is divided into sixteen books, and the laws which compose each title are arranged in chronological order.

The body of laws thus prepared by the emperor of the east was immediately adopted by the emperor of the west. A very curious document, containing the "Gesta in Senatu Urbis Romæ de recipiendo Theodosiano Co-

 dice," has been discovered by Clossius. At this period the Roman senate only exhibited a shadow of its former greatness: the stern and dignified republicans had long been supplanted by the minions of an imperial court; and a senate, possessing a very slender remnant of authority, had been embodied in each of the two great divisions of the empire.[1] The senate of Rome having assembled on this occasion, one of the consuls, Anicius Acilius Glabrio Faustus, proceeded to acquaint the fathers with the legislative enterprize of the one emperor, and the zealous concurrence of the other. " Quam rem æternus princeps, dominus noster Valentinianus, devotione socii, affectu filii comprobavit." He afterwards read the constitution, which has already been mentioned, relative to the project of forming two different codes; and this recitation was succeeded by many exclamations in the highest strain of loyalty. In the midst of various expressions of kindness and regard for the consul, the senators hazarded a few suggestions respecting the custody and transcription of this new code of laws; but we perceive no vestiges of free discussion, or of real deliberation, which always implies the power of adopting either the one or the other of two conflicting opinions. They might presume to regulate certain matters of detail, but were without any real influence in the administration of public affairs. In the instance now before us, their chief functions were manifestly confined to the ready approval of what the consul informed them was the will of the emperor.

The Theodosian Code was thus promulgated in the western, as well as in the eastern empire. The Gothic conquerors of the west permitted their Roman subjects to enjoy the benefit and the protection of their own laws; and a compendium of those laws was soon prepared under the auspices of Alaric king of the Visigoths, whose dominions comprehended certain provinces of Spain and Gaul.[2] This collection contains an abridgement of the three codes of Gregorius, Hermogenianus, and Theodosius, together with some novels, or new constitutions, and an epitome of the Institutes of Caius, extracts from the Sententiæ of Paulus, and from the books of Papinian. It was completed in the year 506, " regnante domino Alarico rege, ordinante viro inlustri Goiarico comite;" and we must apparently conclude that the superintendence of the work had been committed to Goiaric, who was doubtless an officer of the king's court. But it has for several centuries been known under the title of Aniani Breviarium, or the Abridgement of Anianus. The different copies appear to have been attested by his signature; and, according to the opinion of Gothofredus, he presents himself, not as the compiler of the book, but merely as the king's referendary.[3] " Anianus, vir spectabilis, ex præceptione D. N. gloriosiss. Alarici regis, hunc Codicem de Theodosianis legibus, atque sententiis juris, vel diversis libris electum, Aduris anno xxii. eo regnante, edidi atque subscripsi." This attestation is followed by a date, which states the day of the month, and repeats the year of the king's reign; and such a date we may suppose to apply to the act of verifying the copy, not to that of compiling the work itself. We might indeed have expected to find the words " edidi atque subscripsi" arranged in a different order, " subscripsi atque edidi;" but this remark is alike applicable, whether we conceive Anianus to have been the compiler, or merely the collater. To the formation of this collection it is highly probable that several individuals contributed their assistance, under the general direction of Goiaric.[4] To all the books contained in the collection, with the exception of the epitome of Caius, is added an *interpretatio*, or explanation. The manuscripts of the Theodosian Code do not all contain the same explanation, and two different explanations are sometimes subjoined to the same law. It appears from the *auctoritas*, or royal sanction, that explanations were inserted by order of King Alaric, and we must suppose others to have been derived from a different source. This ancient commentary is to be found in Gothofredus's edition of the Theodosian Code; and a very cursory inspection of it seems to have betrayed Sir Edward Sugden into the error of supposing that code partly to consist of a digest of the public laws, and partly of the discussions of private lawyers.[5] This commentary obtained so much credit, that it appears in some measure to have superseded the text. When the writers of the middle ages quote the Theodosian laws, they very commonly refer, not to the text, but to the commentary. Such ancient explanations as these are not without some degree of interest or utility;[6] though they cannot but be supposed to bear sufficient marks of the age to which they belong.

It is only in this ancient abridgement that a considerable proportion of the Theodosian Code has apparently been transmitted to our time.[7] For the first edition of the Code, which was printed at Basel in the year 1528, we are indebted to the commendable zeal of Joannes Sichardus. He had access to several manuscripts; but all of them appear to have been so defective, that very many titles are not to be found in his publication, and indeed several books present themselves in the most mutilated form. He has subjoined the ancient *interpretatio*, together with a collection of the *Novellæ Constitutiones* of Theodosius, Valentinian, and other emperors. His edition is without annotations, but in the margin he has inserted various readings. After an interval of twenty-two years, a more complete edition of the Theodosian Code was pub-

[3] Gothofredi Prolegomena, cap. v. Brunquelli Dissertatio de Codice Theodosiano ejusque in Codice Justinianeo Usu: Opuscula ad Historiam et Jurisprudentiam spectantia, p. 68. Halæ Magd. 1774, 8vo. Savigny's Geschichte des Römischen Rechts im Mittelalter, Bd. ii. S. 42.—The more common opinion is however maintained by Schulting, *Jurisprudentia Ante-Justinianea*, præf. and by Hugo, *Geschichte des Römischen Rechts*, S. 732. " Codicem Theodosianum exscribi jussit," says Cironius, " ut illo uterentur quod Anianius cancellarius suus Aduris promulgavit, cum interpretationibus suis, sub titulo Legis Romanæ." (Observationes Juris Canonici, p. 72. Tolosæ, 1645, fol.)

[4] We therefore adopt the opinion of Gothofredus, that in the following passage Sigebertus Gemblacencis has misunderstood the proper sense of the word *edere*: " Anianus vir spectabilis, jubente Athalarico R. volumen unum de Legibus Theodosii imperatoris edidit; et monente Oruntio episcopo librum Joannis Chrysostomi in Matthæum de Græco in Latinum transtulit." (De Scriptoribus Ecclesiasticis, p. 101. edit. Fabricii.)

[5] Sugden's Letter to James Humphreys, Esq. p. 53. third edit. Lond. 1827, 8vo.

[6] This collection of laws, says the archbishop of Tarragona, is accompanied " cum interpretationibus non ineptis." (Augustinus de Nominibus Propriis του Πανδεκτου Florentini, not. col. 27. Tarracone, 1579, fol.) The merits and defects of these interpretations are minutely discussed by Gothofredus, Prolegomena, cap. vi. See likewise Savigny's Geschichte, Bd. ii. S. 54.

[7] Respecting the newly discovered manuscripts of this Breviarium, the reader will find much information in Haubold's Opuscula, vol. ii. p. 897, and in the preface to the same volume.

lished at Paris by Jean du Tillet, or Tillius, who has however omitted the ancient commentary. In 1566, an edition was published at Lyon by Cujacius, who, among other appendages, has subjoined the ancient commentary, and a collection of the Novels. According to the title-page, the sixth, seventh, eighth, and sixteenth books, "nunc primum prodeunt, cæteri aucti sunt innumeris constitutionibus." Another edition by the same illustrious civilian, but without his name, was published at Paris in 1586; and, in the course of the same year, his name appeared in the title of an edition printed at Geneva. These were followed by other editions of the Theodosian Code; and all the editions include other reliques of ancient jurisprudence.

But the great expounder of the Theodosian Code was Jacobus Gothofredus, or Godefroy, who was born at Geneva in 1587, and died there in 1652. Having at an early age been appointed to a law-professorship in his native city, he acquired a very high reputation as a lawyer of deep and extensive erudition, and in this respect he is only equalled by Cujacius. To his ample stores of philological learning he added a masterly knowledge of history, both civil and ecclesiastical; his industry appears to have been indefatigable, and his reading unbounded. Uniting with his other qualifications a complete knowledge of ancient jurisprudence in all its branches, and applying to his multifarious investigations an acute understanding and a sober judgment, he has produced various works which rise very far above the ordinary standard; but the great and lasting monument of his talents and learning is his edition of the Theodosian Code, on which he bestowed the assiduous labour of thirty years. Thirteen years after his death, it was published under the superintendence of Antoine Marville, professor of law in the university of Valence, who with no small assiduity and perseverance digested his papers into a proper form.[1] If the illustrious civilian of Geneva had himself prepared this edition for the press, it would doubtless have appeared to greater advantage; but even in its present state it is a work of the highest value to the lawyer and to the historian; it is indeed an immense storehouse of juridical and historical knowledge. The commentator has collected a stupendous mass of learning, and his information is derived from every accessible source. To the text of the Code he subjoins the ancient explanation: this is followed by his notes, in which he adverts to the various readings, to the emendation of the text, and to the parallel or conflicting passages in the Theodosian or Justinian laws; and the illustration of each title is completed by his ample commentary, in which he discusses the scope and tendency of the various enactments, and pours around every subject of importance an immense stream of erudition, drawn from the deepest recesses of jurisprudence and history. But in addition to his perpetual commentary, he has composed different tracts which greatly contribute to the elucidation of this collection of laws. "Immortale opus est," says Hugo, "quod Gothofredus perfecit, in quo neque præivit ei quisquam neque ejus vestigia premere ausus est. Nemo Codicem Theodosianum illustrare studuerat; qui primus id consilium cepit, ita quoque perfecit, ut præter spicilegium nil prorsus superesse videretur."[2]

About seventy years after the appearance of this edition, the Theodosian Code, with the commentary of Gothofredus, was republished by John Daniel Ritter, who commenced his undertaking when he was professor of philosophy at Leipzig, and completed it after he had been appointed professor of history at Wittemberg.[3] For a task of this kind he possessed eminent qualifications; being familiarly acquainted with the Roman law and history, he was equally conversant with ancient literature, and he displayed the talents of a skilful critic.[4] To his edition he has added various prefaces, and many shorter notes, and has corrected the text by the collation of manuscripts, and of the former editions. He has reprinted the spurious appendix published by Sirmond, a French Jesuit of uncommon erudition;[5] and to the Novels, which had received no illustration from Gothofredus, he has subjoined many annotations.

The discovery of the Institutes of Caius gave a renovating and powerful impulse to the civilians of the continent; and the recesses of many libraries were explored, in the eager expectation of detecting other reliques of ancient jurisprudence. In the public library at Turin, Professor Peyron discovered a mutilated and undescribed volume in large octavo; and on a more particular examination he found that it was a palimpsest. This volume, as he is led to conjecture, had formed a part of the literary reliques collected in the monastery of Bobbio, which was founded by St Columbanus, a native of Ireland, about the beginning of the seventh century. The second writing consisted of Julius Valerius's Latin version of a narrative of the exploits of Alexander the Great, written by a Greek bearing the name of Æsop. On the application of a proper acid, this version, written with evanescent ink, was very easily effaced, and the more ancient writing became disentangled. Peyron supposes that this manuscript of the Code was transcribed during the earlier part of the sixth century; but, according to Mai, the peculiarities of writing rather belong to the century following. In this manner are preserved thirteen leaves, comprehending portions of the first five books, and two pages which contain a fragment of the sixth book of the Theodosian Code. Nor are these leaves without mutilation: the vellum, in the course of its preparation for a new purpose, has been cut at one side, so that in one page the beginning, and in another the end of the lines, are regularly shorn away; and, in some instances, the tops or bottoms of the leaves are likewise curtailed.[6]

About the same period when Peyron made this discovery at Turin, a similar discovery was made at Milan by Dr Clossius, who is now a professor of law in the university of Dorpat. In the Ambrosian Library he found a quarto volume, containing the treatise *De Officiis*, and several of the orations of Cicero, the Institutes of Justinian,[7] a portion of *Aniani Breviarium*, and *Rhythmus de Assumptione Virginis Mariæ*. The manuscript, which he supposes to belong to the middle of the twelfth century, is written in small, regular, and not inelegant characters, but with pale ink; and the different works contained in the volume appear to have been transcribed by the same hand. The "Gesta in Senatu Urbis Romæ de recipiendo

Theodosiano Codice," which we have already recommended to the notice of our readers, cannot but be regarded as a very curious document; and, besides this historical relique, he has rescued from oblivion a considerable number of constitutions, chiefly belonging to the first book of the Theodosian Code.[1] The new materials thus prepared by Peyron and Clossius, have been incorporated with the older stock, and have received much additional illustration from Dr Wenck, the late eminent professor of the civil law in the university of Leipzig.[2] The first five books of the Code, which long appeared so defective and mutilated, are now exhibited in a form materially improved; nor will his annotations be despised, even by such readers as are most familiarly acquainted with those of Gothofredus and Ritter. His notes are sufficiently copious, and afford abundant proofs of the extent of his erudition, and the soundness of his judgment.

After the interval of a century, the example of Theodosius was followed by Justinian. To ten individuals learned in the laws he in the year 528 entrusted the important task of compiling a new code; and at the head of this commission he placed Tribonian, who makes so conspicuous a figure in the history of his reign.[3] The materials for their undertaking were contained in the three codes which have already been mentioned, and in the constitutions of the intervening emperors. Their collection includes the edicts and rescripts of a long series of princes, from Hadrian to Justinian; and they were authorized to select what was most important, to retrench what was superfluous, to rectify what was erroneous, and even to consolidate several constitutions into one. This task they performed with sufficient dispatch: the new code, which was to supersede all the former, received the imperial sanction on the 7th of April 529. But soon after its completion, Justinian found it necessary to issue fifty new decisions, for the purpose of reconciling conflicting principles; and having in the course of a very few years promulgated various other constitutions, he granted a commission to Tribonian and other four persons to revise the code, and insert the additional laws in their proper places. The first edition was suppressed, and the new edition, *Codex repetitæ prælectionis*, was sanctioned on the 16th of November 534. It is divided into twelve books, and each book into a variety of titles.

During this interval, however, Tribonian had been engaged in a work of greater difficulty. On the 15th of December 530, he had been appointed, along with sixteen associates, to prepare a general digest of legal science, not from the edicts and rescripts of the emperors, but from the writings of those lawyers who enjoyed the highest reputation in the forum.[4] The work which they thus compiled contains a very copious collection of legal principles and legal discussions, exhibiting one of the most remarkable specimens of ancient genius and ancient wisdom. It is divided into fifty books. Dr Bluhme has with much labour and ingenuity attempted to ascertain the general principle of arrangement in the titles of which the different books are composed; and his theory has obtained the approbation of Hugo, and other most competent judges. He supposes that the commissioners appointed by Justinian were divided into three sections, and that to each section was assigned the task of extracting the proper materials from a particular series of works. We are thus to expect a triple series in each title: the deviations from this general plan he conceives to be but inconsiderable; and for particular modifications he discovers an obvious and intelligible reason. The first series commences with the commentaries on Sabinus, the second with those on the *Edictum Perpetuum*, and the third with the works of Papinian. He has pursued his enquiries through many minute details, in which we cannot at present accompany him, but must content ourselves with referring to his elaborate *Ordnung der Fragmente in den Pandectentiteln*.[5]

After the completion, but before the publication of the Digest or Pandects, the emperor employed Tribonian, Theophilus, and Dorotheus, to prepare a short and elementary work as a standard introduction to the study of the law. This work is professedly compiled from more ancient treatises of the same nature, and particularly from the Institutes of Caius, whom Justinian styles "Caius noster." The discovery of this latter work is of great importance in illustrating the text of the imperial Institutes, which have for so many centuries retained their place in the schools of jurisprudence, and have so generally served as models to those who in modern times have undertaken to write elementary treatises of law. "This little work," says Dr Bever, "is so truly admirable, both for its method and conciseness, as well as for the elegance of its composition, that it has been imitated by almost every nation in Europe, that hath ever made any attempt to reduce its own laws to a regular and scientific form."[6] It is worthy of remark, that those who are unacquainted with the Institutes and Pandects, are unacquainted with the full compass of the Latin language.[7] The terse and appropriate phraseology with which they so frequently abound, was transfused from the productions of a purer age; nor is it wonderful that they should occasionally be debased by a grosser mixture. "It is remarkable," as Mr Hume has observed, "that in the decline of Roman learning, when the philosophers were universally infected with superstition and sophistry, and the poets and historians with barbarism, the lawyers, who in other countries are seldom models of science or politeness, were yet able, by the constant study and close imitation of their predecessors, to maintain the same good sense in their decisions and reasonings, and the same purity in their language and expression."[8]

[8] Hume's Hist. of England, vol. iii. p. 300

The Institutes were sanctioned on the 21st of November 533; and on the 16th of December, the emperor issued two constitutions, the one in Latin and the other in Greek, by which he confirmed the Institutes, Code, and Pandects, and imparted to them the force and validity of law in the forum, and commanded them to be taught in the schools of Rome, Constantinople, and Berytus. Justinian survived till the year 565, and during that long interval he promulgated many new laws. A collection was at length formed of his Novels, or new Constitutions, to the number of one hundred and sixty-eight. The greatest part of them appear to have been originally written in Greek; some were however written in Latin, and others were at the same time exhibited in both languages.[1] These are followed by thirteen Greek edicts of Justinian, which properly conclude the *Corpus Juris Civilis*, although the common editions comprehend various Novels of Leo,[2] and some other emperors, together with other ancient documents, all of which are only to be considered as appendages.

The task of compiling the Institutes, as we have already seen, was committed to Tribonian, Theophilus, and Dorotheus, of whom the two latter are described as *antecessores*, or public professors of law. Whether one of these was the same Theophilus who wrote a Greek paraphrase of the Institutes, has been long and much disputed among civilians: to recapitulate all the arguments which have been urged on both sides of the question, would require too much time and space; we shall therefore content ourselves with stating, that we are strongly inclined to adopt the opinion of those writers who maintain their identity, and with referring the more curious reader to the ample discussions of Mylius and Reitz.[3] Theophilus was a professor at Constantinople, and Dorotheus at Berytus. During the reign of Justinian, the two imperial cities, together with Berytus, were the only places, within the limits of the empire, where public schools of law were established, or indeed where law was permitted to be publicly taught.[4] Berytus, which the emperor describes as a most beautiful city, was situated on the coast of Syria: here a school of jurisprudence was founded during the third century, and it was long frequented by a numerous train of students; but its prosperity was first interrupted, and was finally subverted, by some of the great convulsions of nature. In the year 384 the town was greatly injured by an earthquake, and in 554 it was visited by another earthquake, which left it a heap of ruins. Some professors and a multitude of students perished in this common calamity: the surviving professors transferred their school to Sidon, and the surviving inhabitants made a vigorous effort to raise a new city from the ruins of the old; but another calamity awaited them, and this famous seat of jurisprudence was totally consumed by fire.[5]

The paraphrase of Theophilus is of great utility and importance in explaining the text of the Institutes. He has not servilely confined himself to the original, and his work in a great measure supplies the place of a perpetual commentary. It is a book indispensably necessary for every more learned and inquisitive student of the civil law. This paraphrase is not indeed entirely free from errors: Reitz conjectures, and not without a considerable degree of plausibility, that Theophilus had dictated it to the students of Constantinople, in the exercise of his functions as a public expounder of the law; and that for its transmission to posterity we are solely indebted to copies taken by his auditors, and uncorrected by himself. To this valuable relique the attention of modern lawyers was first directed by Angelo Poliziano, who died at a premature age in the year 1494. He was a person of singular talents and attainments, who only required a greater length of days to have earned the highest reputation. To the celebrity of an Italian and Latin poet, and of a classical critic, he was solicitous to add that of a civilian; and he was likewise the first individual who attempted a collation of the renowned Florentine manuscript of the Pandects.[6]

Of the Pandects, different Greek versions have been mentioned by different writers. One version has been ascribed to Thalelæus, who was an antecessor in the time of Justinian; but Pohl and Heimbach have shewn that there are no sufficient grounds for believing that he undertook such a task.[7] Another translation is mentioned by Matthæus Blastares as having been executed by Stephanus, an advocate of Constantinople, who had been conjoined with Tribonian in the commission for compiling the original work. The Code was likewise translated into Greek: the translator is supposed to be the person who, in the scholia of the Basilica, is repeatedly described as Κωδικευτης. To many of the judges, as well as the suitors, in the eastern empire, Latin must evidently have been an unknown tongue. When the seat of empire was transferred from Rome to Byzantium, the first emperors were anxious to transfer the use of the Roman language, and for a considerable time this continued to be at least the language of the court. Teachers of Roman eloquence were established in the second metropolis, and they doubtless found many pupils among the youth who aimed at a fashionable education, or were ambitious of preferment; but it was not to be expected that the great body of the people should be induced to unlearn one language, and to acquire another.

During the interval which elapsed between the reign of Justinian and that of Basilius, there were many Greek writers on the Roman law; and not a few names have been recovered from the wreck of time by Lambecius, Suarés, Asseman,[8] and other learned enquirers. Basilius, who has obtained a conspicuous place among the legislators of the empire, derived his lineage from Armenia, but was himself born in Macedonia, and is commonly known by the name of Basilius the Macedonian. He rose from an origin sufficiently humble, and after having been a groom, he be-

came sovereign of the east. The eastern empire, in which the Greek language was vernacular, was governed by a collection of laws chiefly written in Latin; and the different versions which had been executed were without the sanction of public authority. It was therefore his object to select such enactments as were still in force, and having digested them into the form of a regular code, to invest them with the imperial sanction. This great undertaking he did not live to complete. He died in the year 886, and was succeeded by his son Leo, surnamed the Philosopher. The body of Greek laws was completed under his direction: the date of its promulgation has not been ascertained; but as the student is referred to it in Leo's Ecloga, which was written in the year 910, the *Basilica* must have been in circulation before that period. Leo ended his reign and his life in the year 911, and was succeeded by his son Constantinus Porphyrogennetus, when only seven years of age. From this learned prince the *Basilica* appear to have received their final revision. Theodorus Balsamon, in his commentary on the Nomocanon of Photius, describes the revised edition as την τελευταιαν ἀνακαθαρσιν;[1] and, according to the opinion of Heimbach, it was not divulged before the year 945.[2]

It has long been a current opinion that, in the western empire, all knowledge of the civil law became extinct, and was not revived till after the lapse of several centuries. "All the world knows," says Lord Kames, "that the Roman law, after being buried in oblivion for ages, came to be restored in Italy by an accident. The very books of that law were understood to be lost past recovery, till a copy of the Pandects was found in the town of Amalphi *anno* 1127,[3] by Lotharius the emperor when he took that town, in the war he carried on against Rodger king of Sicily and Naples. The knowledge of it increased so fast, that it was taught publicly by Vacarius at Oxford about the year 1150, during the reign of king Stephen.[4] This was as swift a progress as any science can be supposed to make."[5] A more recent writer has added something to the old stock of speculation. "The fortunate, or perhaps unfortunate discovery of the Roman *code*, at Amalfi in Italy, produced a great change in the institutions of almost every country in Europe. The dignified clergy of that day immediately perceived how advantageous the adoption of the regulations of Justinian would prove to them; and the popes, who then pretended to dispose of the throne of the Cæsars, were eager to support the arbitrary edicts of emperors, who, like themselves, affected to think that both their persons and their rescripts were inviolable. The neighbouring countries cheerfully submitted to the change, and thus engrafted slavery and the civil law on that even-handed Gothic jurisprudence, which had ensured freedom to all the northern nations."[6] This philosophic speculator, who thus attempts to twist a rope of sand, has not even arrived at the point of distinction between the Pandects and the Code. So true it is that when an English writer ventures to speak of the Pandects, he generally finds his way to be dark and slippery.

It was maintained by Taurellus, Augustinus, Brenkman, and other learned civilians, that all the copies of the Pandects known to be extant are derived from this famous manuscript, which was first deposited at Pisa, and afterwards removed to Florence.[7] This opinion was zealously opposed by the Abate Grandi, professor of mathematics in the university of Pisa, whose *Epistola de Pandectis* was first printed in the year 1726.[8] The course of his enquiries also led him to call in question the traditionary tale respecting the marvellous resuscitation of the Roman law after the siege of Amalfi. Various writers had incidentally maintained the opinion which he adopts; and it had recently been maintained in a separate work by D'Asti.[9] The story of the manuscript seized as a warlike booty, he treats as a mere fiction; and Muratori has remarked, that the earliest authority for this anecdote of the siege is Raynerius de Grancis, a writer of the fourteenth century. To Grandi's work, which attracted no small degree of attention, an answer was published by Bernardo Tanucci, professor of the civil law at Pisa;[10] nor was the mathematician tardy in replying.[11] Tanucci soon prepared a copious rejoinder.[12] Grandi continued the controversy, under the assumed name of Bartolo Luccaberti;[13] and his antagonist concluded his exertions, by enlarging his first epistle, and translating his second defence into Latin.[14] In these disquisitions, they were succeeded by Schwartz, a learned German, who rejected the notion that all the modern copies of the Pandects are derived from the Florentine manuscript.[15] Brenkman, who had devoted so much

15 Schwartz published a disquisition, "An omnia Pandectarum Exemplaria, quæ adhuc extant, e Florentinis manaverint." Altorfii, 1733, 4to.

time and attention to this manuscript,[1] and had formerly maintained the opposite opinion, endeavoured to refute the arguments of Schwartz as well as Grandi;[2] and the same cause, which we do not however espouse, was after a short interval defended by Guadagni, professor of the civil law at Pisa.[3] But the history of the Roman law during the middle ages has recently been investigated with so much ability, and with such perseverance of research, that on this subject the labours of all previous writers appear to be of little comparative value: Savigny's work is indeed one of the most remarkable productions of the age in which we live.[4] After many delays this work was completed in 1831, shortly before the author's death. The extinction of the Roman law with the Western Empire, and its accidental revival after the lapse of six hundred years, will henceforth be viewed as one of the numerous romances of history; but the researches of this very able man, we are sorry to add, are little known or appreciated in England, where the legend of Amalfi is permitted to retain much of its original freshness, and where historical jurisprudence is more imperfectly understood than in any other learned country of Europe. (D. I.)

CIVIL LIST. Under this term were formerly comprehended "all the heads of public expenditure, excepting those of the army, the navy, and the other military departments;" but it is now confined to the expenses proper for the maintenance of the royal household and the dignity of the crown, the amount of which is fixed by parliament on the accession of the sovereign. For particulars regarding the civil list, see ENGLAND.

CIVIL *State*, the whole body of the laity or citizens, comprehending all orders of men not included under the military, maritime, or ecclesiastical states.

CIVIL *Year*, the legal year, or annual account of time which a government appoints to be used within its own dominions; so called in contradistinction to the natural year, which is measured by the revolution of the heavenly bodies.

CIVILIAN, one who is skilled in the Roman law; a professor or doctor of civil law. It is also sometimes applied in a more extended sense to one versed in law and government.

CIVITA CASTELLANA, a fortified episcopal town of the Papal States, delegation and 17 miles E.S.E. of the city of Viterbo. Pop. 3300. It occupies the site of *Falerium Vetus*, well known in history from the celebrated story of Camillus and the schoolmaster. Portions of the ancient walls, tombs, and sepulchral chambers are still to be seen. After the destruction of this city by the Romans in B.C. 241, the second or *Falerii Novi* was built in a plain about 4 miles distant. The ruins of this town present some of the most extraordinary specimens of ancient military architecture now extant, consisting of walls nearly perfect, quadrilateral towers, and gateways; while within there are remains of an ancient theatre, &c.

CIVITA DI PENNE, a town of Naples, province of Abruzzo Ulteriore I., 10 miles W. of Pescara. Pop. 9600. Under the name of Pinna it was the chief city of the Vestini, and is celebrated in the history of the Social war for its obstinate resistance to the Roman army by which it was besieged. It has still some remains of ancient buildings, and is noted for the manufacture of artificial flowers.

CIVITA VECCHIA, a city of Italy, capital of a cognominal delegation of the Papal States, on the Mediterranean, 38 miles W.N.W. of Rome. Lat. 42. 4. 38. N., Long. 11. 44. 52. E. The town is well built, and surrounded by walls, but the streets are generally narrow. It has several churches and convents, lazaretto, theatre, arsenal, warehouses, building-docks, prisons, &c. It is the principal seaport of the Papal States; and steamers between Marseilles, Naples, and the Levant, regularly touch here, so that the arrivals and departures of steamers are seldom less than 30 a month. The harbour, originally constructed by Trajan, is formed by three moles—two projecting from the mainland, and fronted by the third, on the south extremity of which is a lighthouse, with a lantern 74 feet above the level of the sea. There are from 14 to 18 feet water in the port, and the S. entrance has from 8 to 4 fathoms. The imports are chiefly cotton, woollen, silk, and linen stuffs; coffee, sugar, and other colonial products; salt and salted provisions, wines, jewellery, glass, and earthenware. The chief exports are staves, bark, wheat, coal, wool, cheese, skins, and alum. Civita Vecchia occupies the site of the Roman *Centum Cellæ*. On the destruction of that town by the Saracens in 828, the inhabitants removed farther inland, but returned to the former site in 854. From this circumstance the city derives its name of Civita Vecchia, or old town. It was made a free port by Clement XII. Pop. 7000.

CIVRAY, an arrondissement of the department of Vienne, in France, containing 460 square miles. It is divided into 5 cantons, and these again into 48 communes, the inhabitants of which amount to 45,675. Civray, which gives its name to the arrondissement, is situated on the right bank of the Charente, in a fertile district. It contains 328 houses, and 2100 inhabitants. In the neighbourhood there are considerable quarries of marble. Long. 0. 9. E., Lat. 46. 10. N.

CLACKMANNAN, the capital of the shire of the same name, is pleasantly situated on an eminence gently rising out of a plain stretching from east to west to the height of 190 feet above the level of the Forth, and commanding an extensive view from the summit. It consists of one long street, which runs up the acclivity to the gate of the park surrounding Clackmannan tower, a tall and massive building.

A small plain immediately to the west of this tower formed the site of the palace of Robert Bruce—every vestige of which has long since disappeared. The church of Clackmannan, which is situated a little south of the principal street, is a handsome modern structure in the Gothic style. Pop. of parish (1851) 5802.

CLACKMANNANSHIRE, one of the counties of Scotland, situated between 56. 5. and 56. 14. north latitude, and between 3. 33. and 3. 56. west longitude from Greenwich. It is bounded on the south and south-west by the river Forth, which separates it from Stirlingshire, on the south-east by Fifeshire, and on every other side by Perthshire. It is the smallest county in Scotland, being little more than eight miles in length, and, at a medium, six miles and a half in breadth; thus extending over fifty-two square miles, or 33,280 acres. But its value is much greater than in the ratio of its extent. About three-fourths of its surface are under cultivation (a greater proportion, with the exception of East Lothian, than that of any other county of Scotland); and it abounds in the useful minerals, which have long been wrought upon a very extensive scale.

Between the Ochil Hills, which form the northern boundary of this district, and the rich alluvial tracts on the banks of the Forth, which winds along in a very irregular line on its opposite extremity, there is a considerable variety of surface. An elevated ridge rises on the west, and, running through the middle of the county, spreads itself gradually till it reaches the eastern boundary, skirting the alluvial or carse lands on the south, and the vale of Devon on the north. And still farther to the north, the Ochil Hills, the highest of which, Bencleuch, in the parish of Tillicoultry, rises nearly 2500 feet above the level of the sea, form a very picturesque landscape, having their generally verdant surface broken by bold projecting rocks and deeply indented ravines, the beds of many a pellucid stream, with coppice and thriving plantations occasionally interspersed. These hills protect the lower grounds from the piercing winds which blow from the north and north-east, and give Clackmannanshire some advantage, in regard to climate, over the adjoining counties.

The only streams worthy of notice which traverse this county are the Devon and the Black Devon, or, as they are often called, the North Devon and South Devon. The Devon rises in the county of Perth, and, descending with impetuosity from the Ochils, where its course is to the east, makes a very sharp turn towards the west. It then continues its course in that direction through the pleasant vale already mentioned, and falls into the Forth at the village of Cambus. Exclusive of its windings, the course of this river is more than twenty-six miles, though the distance in a direct line from its source to its embouchure does not exceed six miles. It has long been remarkable for the deep and dark chasms which it has worn in the rocks, and through which it flows in the earlier part of its course, being in some places hardly visible. The *Devil's Mill*, so called from the supposed resemblance of the sound of the water to that of machinery; the *Rumbling Bridge*, a very narrow and unguarded pass across a chasm 90 feet deep; and the *Cauldron Lynn*, where the water is perpetually agitated in the immense cauldron-like excavations which it has formed in the rock—are much visited by the lovers of natural scenery. Though this river is liable to be suddenly swelled by rains, and frequently descends in torrents overflowing its banks, it is in general of no great depth, but might be rendered navigable for small vessels at a moderate expense, to the effect of bringing 10,000 acres of coal within reach of water-carriage.

The Black Devon has its source in the county of Fife, flows westward in a direction nearly parallel to the Devon, and falls into the Forth near Clackmannan. Many mills and coal engines are set in motion by the waters of this river, whose whole course is over coal strata. In a dry season it is an inconsiderable stream, the greater part of its waters being then collected into reservoirs for the supply of machinery.

The Forth is navigable as far as it forms the boundary of this county. Ships of 500 tons burden run up as far as Alloa. Its windings, or *links* as they are called, are very remarkable. The distance from the quay of Alloa to that of Stirling, measured in the middle of the stream, is 17 miles, and to the bridge of Stirling it is 19½, whereas the distance by land from the latter place to Alloa does not exceed 7 miles. A little above Alloa there are three islets in the river, the largest containing more than 70 acres. A remarkable ledge of rock stretches across the Forth below the two smaller islets, which obstructs the passage of vessels of more than 60 tons burden, and where it is fordable at low water of spring tides. The breadth at this place being only about 500 yards, it was long since proposed to throw a bridge over it, the expense of which was estimated at L.70,000. Mr Rennie, the celebrated engineer, made a survey with a view to a bridge at the Alloa ferry, which he declared to be practicable at an expense of L.150,000; a work which has never been attempted. The passage, however, has of late been improved by means of new piers and steam-boats. The estuary of the Forth, for several miles above and below Clackmannan, exhibits a singular phenomenon in its tides, which rise there from 16 to 22 feet. During neap tides in good weather, and sometimes also during spring tides, if the weather be uncommonly fine, after the water has flowed for three hours, it retires in an hour and a half nearly as far as the line from which it had begun to flow, but returns immediately, and in an hour and a half more reaches the same height it had attained before. This flux and reflux takes place both in the flood and ebb tides, so that double the usual number of tides occur in this part of the river. In very boisterous weather, however, these *lecky tides*, as they are called by sailors, are not regular, the water then only rising without any perceptible current, as if two tides were acting against each other.

The soils of the arable land of Clackmannanshire are in general productive and well cultivated; though the greater part of the elevated range which is interposed between the carse lands on the Forth, and the vale of Devon at the base of the Ochils on the north, consists of inferior soils, often incumbent on an impervious clay. All the crops commonly raised in Scotland grow luxuriantly on either side of this tract, which also contains within itself a considerable proportion of valuable soil. From the rental of the abbacy of Cambuskenneth, founded in 1147, it appears, that wheat was cultivated on the *links* of the Forth at a very early period; yet it is certain that fifty years ago fields of this grain were only occasionally to be met with in the county. As a proof how early and well the carse lands near Alloa had been cultivated, it may be mentioned, that more than a century ago some farms in that quarter paid as much grain and other kinds of produce, in name of rent, as the present money-rent of similar soils would purchase at the average prices of the last twenty-five years. The farms would be thought small in other counties; few of the arable ones exceeding 200 Scotch or 250 English acres, and the far greater number being below 100 acres. The rent of the county was returned to the collector of the property-tax for the year ending in April 1811, at L.32,047, 12s.; so that, after making allowance for that part of the surface which is covered by water, or otherwise altogether unproductive, every acre must have paid at least 20s. upon an average of all soils and situations. At the same time, the rent of the houses was stated at L.2827, 5s. The old valuation, by which the land-tax and county rates are apportioned, is L.26,482, 10s. 10d. Scots, or L.2206, 17s. 7d.

sterling, of which somewhat more than a third belongs to estates held under entail. The richest carse land under current leases now (1854) lets for ten bushels of wheat a Scotch acre, payable by the fiars, and in the measure of the county. Good carse land commonly rents at three bolls an acre, one of which is wheat, one barley, and one oats. The first effective thrashing machine in Scotland was constructed at Kilbagie, in the parish of Clackmannan, in 1787, by Mr George Meikle, the son of its celebrated inventor; and the last one, it is believed, at which old Meikle himself worked, is on the estate of the Earl of Mar, near Alloa. One of the greatest disadvantages which the agriculture of this district labours under is the want of limestone, of which, however, very considerable quantities are brought from Rescobie limeworks, and afterwards calcined in the county, where coal is always plentiful and cheap. Limeshells are also imported to a considerable extent from the Earl of Elgin's works in Fife.

This small county is rich in minerals. Silver, copper, lead, iron-ore (*hæmatites*), cobalt, and arsenic, have all been discovered in the Ochil Mountains, between Airthry and Dollar; but, after having been wrought for a time with little success, the labour was discontinued. The operations, however, were not conducted upon an extensive scale; in no instance did the miners penetrate below the level of the plain from which the Ochils rise; and it is still believed that these hills abound in valuable metallic veins, ready to reward more skilful and enterprizing adventurers. Ironstone is wrought to a considerable extent for the Devon iron-works, in the parish of Clackmannan. It is found either in beds, or in oblate balls imbedded in slaty clay, and yields from twenty-five to thirty per cent. of iron. That obtained from the mine formerly worked at Vicar's Bridge, near Dollar, afforded, it is said, above forty per cent.

The Abbey Craig, near Stirling, a great mass of greenstone rock, crystallized in the internal structure and rudely columnar in its external appearance, deserves to be particularly noticed in this view of Clackmannanshire, from its having afforded a very useful substitute, in the manufacture of flour, for the French buhr-stones, which it was so difficult to procure during the last war. This discovery was made by a miller of the name of James Brownhill, then employed at the Alloa mills. Several hundreds of these millstones are now working both in England and Scotland, and are found to be in some respects almost equal to the buhr. The Society for the Encouragement of Arts in London presented this ingenious person with a hundred guineas for his discovery, after they had received the most satisfactory proofs of its great importance.

Coal has been wrought for two hundred years in this county. The quantity at present annually obtained may be estimated at 260,000 tons, of which a great part is shipped at Alloa, Clackmannan Pow, and Kennetpans, for foreign ports; and large quantities of coal are also now conveyed along the railways which extend to Aberdeen. In the scale of working, the collieries stand thus,—1. Alloa; 2. Clackmannan; 3. North Sauchie; 4. Tillicoultry; 5. Kennet; 6. Sheerdale. It is all bituminous or common coal of a good quality; but no smithy or caking coal has yet been discovered. The thinnest seam which has been wrought is 27 inches thick; and in a depth of 105 fathoms, there are nine seams of more than this thickness. The thickest that has yet been discovered is about seven feet. The strata which compose the coal-field are varieties of sandstone, shale, fire-clay, and argillaceous ironstone. Limestone is found among the lowest beds of the coal strata. Organic remains of shell-fish and plants abound in them; and of the latter, many are of genera now found only in the equatorial regions. Carbonic acid gas, termed chokedamp, is the most abundant of the noxious vapours found in the coal-mines of this field. Carburetted hydrogen, or inflammable air, was never known here till lately, and it is still in small quantity. The great coal-field of Scotland, which passes in a diagonal line from the mouths of the Forth and Tay to the Irish Sea, is bounded by the Ochils. No coal has been found to the north of them, excepting at Brora, in the county of Sutherland.

Machinery for drawing water from the mines was constructed and much improved in this county, before the invention of the steam-engine. The Alloa colliery is drained by an overshot water-wheel, 30 feet diameter, which lifts the water from the depth of 300 feet. The Sauchie collieries are drained by powerful steam-engines: that employed by the Devon Company, in particular, is one of great power, and is capable of drawing water from the depth of 280 feet. The Stirling and Dunfermline railway runs through the county of Clackmannan, and affords very great facilities for the transmission of goods and the conveyance of passengers. From the Devon iron-works, and the various collieries of the county, as well as from the great brick and tile works, there are railways to Alloa.

At the Alloa colliery the workmen have for a great number of years had a court composed of five of their own number, appointed annually by the proprietor of the works. By this court all differences amongst themselves are settled. The highest fine exacted is half a guinea, and all the fines are put into a general fund for the support of the poor.

Under the head of manufactures, the distilleries of this county formerly constituted by far the most prominent and considerable branch. In this small district there were 40 years ago no fewer than six large distilleries. Of these, Kilbagie and Kennetpans paid to government an excise-duty greater than the land-tax of Scotland; the former alone paying no less at one time than about half a million sterling. Previously to 1788, the quantity of grain annually consumed at Kilbagie, exceeded 60,000 bolls (45,000 quarters); while 700 cattle and 200 swine were annually fattened upon the grains and dreg. The saving in the stock of food for man effected by the stoppage of the distilleries was therefore much less considerable than had been imagined; an acre of barley used in distillation yielding nearly as much animal food as an acre of middling pasture. It is understood that cattle may be fattened in a complete manner, in the proportion of two, of 50 stones avoirdupois each, for every gallon of a still, when working from grain; affording the means, at the same time, of enriching the soil for future crops, by the abundance and good quality of the manure they produce. For several years there have been only three distilleries in the county. The manufacture of woollen goods and worsted has been long carried on in this county. The following statistics will show the importance which these manufactures have attained in Clackmannanshire. In Tillicoultry, which is the principal seat of the woollen manufacture, there were in 1851 fifteen factories containing 39 sets carding machines, &c., of which nine were self-acting mills of the largest and most approved kind. About 40,000 stones of wool were annually required for the manufactures. The power, partly water and partly steam, required for driving the whole machinery, was 184 horse-power.

In 1811, the total number of persons engaged in the factories was 836 men, 602 women, 352 children—in all 1790.

There are now in the entire county 20 woollen mills, driven by 320 horse-power, employing 2600 persons, and annually consuming 1,800,000 lb. of wool.

At the Devon iron-works, already noticed, about 112 tons of pig iron are prepared weekly, a considerable part of which is used by the foundry at these works. In the parish of Dollar, on the banks of the Devon, a bleachfield was esta-

blished in 1787, of which the water supply and the machinery are excellent. The cloth bleached here consists chiefly of the fine table-linen manufactured at Dunfermline. There is a very complete set of corn-mills at Alloa, besides other mills for various purposes in different parts of the county. In the same town and its neighbourhood there are five breweries, a glass work, a copper work, a rope and sail manufactory, a tannery, a tile and brick work; and in 1832 a steam-engine manufactory was organized.

The port of Alloa is well situated for commerce, and has a substantial well-built quay, and a little above the harbour, a dry dock capable of receiving vessels of large burden; the depth of the water at spring-tides being sixteen feet, and the width of the gates thirty-four and a half. There is a custom-house here, which comprehends the ports of Stirling and Kincardine, and Clackmannan Pow, and at which 155 vessels were registered in 1831, carrying 19,000 tons, and navigated by 1020 men. There are cleared outwards annually, on an average, from 1100 to 1200 vessels, carrying 55,000 tons, and employing about 3300 seamen; and inwards, about 700 vessels, carrying 32,000 tons, and 1800 men. The principal exports are coals, pig and cast iron, ales for London, and British spirits. The annual imports consist, for the most part, of grain for the distilleries and breweries, of which a great proportion is barley from the county of Norfolk, and goods from Leith, Glasgow, Greenock, and London. Timber, iron, and other commodities, are occasionally imported from the Baltic. Alloa is connected by railway with Stirling, Edinburgh, and Glasgow, and communicates by steam-packets with Granton near Edinburgh.

Among the antiquities of this county may be mentioned the ruins of Castle Campbell, originally called Castle Gloom, in a singularly wild and almost inaccessible situation, within a recess of the mountains, above the village of Dollar. The period of its erection and its early history are unknown. In 1465 it became the property of the Argyll family, from whom it derived its present name; and was the ordinary residence of Archibald Earl of Argyll at the time of the Reformation. In this stronghold John Knox found a temporary retreat. In 1644 it was burned by Montrose, and since that time it has been suffered to remain in ruins. The tower of Alloa, built prior to the year 1300, the residence of the Erskines, earls of Mar, now belonging to the representative of that noble family, is in good preservation. The walls are 11 feet in thickness, and the highest turret is 89 feet above the ground. The tower of Clackmannan was long the seat of the chief of the Bruces after the failure of the male line. There is a charter, dated the 9th of December 1359, quoted by Douglas, in which David II. grants to Sir Robert Bruce, whom he there styles his dearly beloved relation, the castle and manor of Clackmannan, with divers other lands within the county. Since the death of Henry Bruce of Clackmannan, in 1772, without a male representative, it has been made a question whether the Earl of Elgin or Bruce of Kennet be now the chief of that royal race.

Clackmannanshire sends a member to parliament, conjunctly with the county of Kinross. By the Reform bill, there are annexed to Clackmannanshire, for the purposes of election, the parishes of Culross and Tullyallan, formerly comprehended in the county of Perth; Alva, formerly belonging to Stirling; and the Perthshire portion of Logie. This arrangement has increased the population to 22,951 souls. Clackmannanshire thus comprehends eleven parishes, the constituency of which now amounts to 1149. There is no royal burgh in this county. Clackmannan, which gives its name to the county, is the only town in it besides Alloa deserving of notice.

There are now legal assessments for the maintenance of the poor in all the parishes of Clackmannanshire.

The numbers of houses and inhabitants for the years 1841 and 1851, are given in the subjoined table:—

Years.	Houses.			Persons.		
	Inhabited.	Uninh.	Building.	Males.	Females.	Total.
1841	3406	111	6	9,386	9,769	19,155
1851	2950	96	53	11,342	11,609	22,951

CLAGENFURT. See KLAGENFURT.

CLAGETT WILLIAM (1646-1688), an eminent divine, who was preacher to the society of Gray's Inn, and chaplain to James II. Archbishop Sharp and Bishop Burnet have both given him a high character. He published a variety of miscellaneous tracts, the principal of which is his "Discourse concerning the Operations of the Holy Spirit." Four volumes of his sermons were published after his death by his brother Nicholas Clagett, father of the bishop of Exeter of that name.

CLAIR OBSCURE. See CLARO OBSCURO.

CLAIR, ST. See CANADA.

CLAIRAULT, or CLAIRAUT, ALEXIS-CLAUDE, was born May 7, 1713, at Paris, where his father was a teacher of mathematics. Under his father's tuition he made so rapid progress in mathematical studies, that in his thirteenth year he read before the French Academy a memoir of the properties of four curves which he had then discovered. When only sixteen, he finished his treatise on *Curves of Double Curvature*, which, at its publication, two years later, procured his admission into the Academy of Sciences, although even then he was below the legal age. Having formed an acquaintance with Maupertuis, Lemonnier, and others, he began his researches on the figure of the earth, the results of which were published in 1743. In his work on this subject he promulgated his famous theorem in regard to the variation of gravity, which has been corrected by Mr Airy. In 1750 he gained the prize of the St Petersburg Academy, for his treatise on the Lunar Theory; and in 1759 calculated the perihelion of Halley's Comet. Towards the close of his life he was regarded as the great rival of D'Alembert. Clairault died at Paris, May 17, 1765. See ASTRONOMY.

CLAMECY, a small town of France, capital of a cognominal arrondissement, in the department of Nièvre, at the confluence of the Yonne and Beuvron, 38 miles N.N.E. of Nevers. Pop. (1851) 6002. It has some remains of its ancient castle, and of the massive walls by which it was formerly surrounded; several Gothic churches, a handsome modern chateau; manufactures of woollen cloths, earthenwares, paper, and leather; and a considerable trade in wood and charcoal, principally with Paris, by means of the Yonne.

CLAMPING, in joinery, the fitting of a piece of wood into a board across the grain, to prevent its warping. Clamp, in a general sense, denotes a piece of timber or iron used to fasten work together.

CLANDESTINE (Lat. *clandestinus*), secret, private, withdrawn from public view; generally used in an ill sense. Thus a marriage is said to be clandestine when performed without the publication of banns and the consent of parents or guardians. See MARRIAGE.

CLANS, in *History*, and particularly in that of Scotland, tribes or septs. The nations which overran Europe were originally divided into many small tribes; and when they came to parcel out the lands which they had conquered, it was natural for every chieftain to bestow a portion, in the first place, upon those of his own sept or family. These all held their lands of him; and as the safety of each individual depended on the general union, each small society clung together, and was distinguished by some common appellation, either patronymic or local, long before the introduction of surnames or ensigns armorial. But when these became

common, the descendants and relations of every chieftain assumed the same name and arms with him; other vassals were proud to imitate their example; and by degrees the same distinctions were communicated to all those who held of the same superior. Thus clanships were formed; and in a generation or two that consanguinity which was at first in a great measure imaginary was believed to be real. An artificial union was converted into a natural one. Men willingly followed a leader whom they regarded both as the superior of their lands and the chief of their blood; and served him not only with the fidelity of vassals, but with the affection of friends. In the other feudal kingdoms, we may observe such unions as we have described, imperfectly formed; but in Scotland, whether they were the production of chance, or the effect of policy, or strengthened by preserving genealogies both genuine and fabulous, clanships were universal. Such a confederacy might be overcome, but it could not be broken; and no change of manners or government has been able, in some parts of the kingdom, to dissolve associations which are founded upon prejudices so natural to the human mind. It is easy to imagine how formidable were nobles at the head of followers, who, counting that cause just and honourable which their chief approved, were ever ready to take the field at his command, and to sacrifice their lives in defence of his person or of his fame. Against such men a king contended with great disadvantage; and that cold service which money purchases, or authority extorts, was not an equal match for the ardour and zeal generated by this patriarchal brotherhood in arms.

Some have regarded the word *clan* as merely a corruption of the Roman *colonia;* but Whitaker considers it as purely British, signifying a *family* or sept.

CLAPHAM, a parish in Surrey, 4 miles S.W. from St Paul's, and one of the most favourite of the suburban districts around London. It has several churches and chapels; a grammar and other schools, orphan asylum, literary institute, savings-bank, &c. The common, extending over 200 acres, is planted with trees and surrounded by handsome houses, and ornamental wood. Pop. of parish (1851) 16,290.

CLAPPERTON, Hugh (1788-1827), a distinguished African traveller, was born at Annan, Dumfriesshire, where his father was a surgeon. Having acquired some knowledge of practical mathematics, including navigation and trigonometry, he was apprenticed at the age of seventeen on board a large vessel which traded between Liverpool and North America. After having made several voyages across the Atlantic, he was impressed for the navy, and sent on board the Clorinde, where his intelligence and activity soon raised him to the rank of midshipman. In 1813 he was sent with a number of others to Plymouth dockyard to be drilled in the improved cutlass exercise, and afterwards drafted on board the Asia, the flag-ship of Vice-admiral Sir Alexander Cochrane, to the crew of which, then on a voyage to Bermuda, he acted as drill sergeant. He was next ordered to the command of a flotilla on the Canadian lakes, promoted to the rank of lieutenant, and soon afterwards to the command of a schooner. In the year 1817, when the flotilla on the lakes was dismantled, he returned to his native country on half pay.

In 1820 Clapperton removed to Edinburgh, where he contracted an intimacy with Dr Oudney, who first directed his attention to the cause in which both were destined to perish. After the return of Captain Lyon, the British government determined on equipping a second expedition for the purpose of exploring northern Africa. Dr Oudney was accordingly appointed to proceed to Bornu as consul, and Captain Clapperton and Colonel Denham were added to the party. After having arrived at Tripoli, they set out early in 1822, in a line nearly south to Mourzook, where they arrived on the 8th of April. Circumstances, however, having prevented them from proceeding farther, Clapperton and Oudney made an excursion to the westward into the country of the Tuaricks, which they penetrated as far as Ghraat, E. Long. 11.

On the 29th Nov. Clapperton, with his fellow travellers, set out for the kingdom of Bornu, and on the 17th Feb. 1823 reached Kouka the capital, where they were well received by the sultan; and remaining here till the 14th Dec., they again set out for the purpose of exploring the course of the Niger. They arrived in safety at Murmur, where Oudney breathed his last in the arms of his companion. Clapperton, however, penetrated alone as far as Sackatoo, N. Lat. 13. and E. long. 6½., which was the extreme point of the expedition in that direction. Circumstances prevented him from proceeding to the Niger, which lay only five days' journey to the westward. On returning to Kouka he was rejoined by Denham, who scarcely knew his emaciated associate. The two travellers then set out for Tripoli, and thence proceeded to England, where they arrived on June 1, 1825. The results of this expedition were embodied in a work containing the travels of Denham, Clapperton, and Oudney.

Immediately after his return Clapperton accepted the conduct of another expedition to Africa, and set out in August 1825, in company with Captain Pearce, Mr Dickson, Dr Morrison, and a youth named Richard Lander as his servant. On this occasion he landed at Badagry, in the Bight of Benin, and immediately commenced his journey into the interior, along with Lander and two of the others. Both of them, however, soon fell victims to the hardships of the journey. In January 1826, Clapperton reached Katunga, the capital of Youriba, and soon afterwards crossed the Niger at Boussa, the place where Park met his untimely fate. In July he arrived at Kano, a city which he had previously visited. Here he left his servant with the baggage, and proceeded alone to Sackatoo, intending to obtain permission from Bello, the sultan of Sackatoo, to visit Timbuctoo, and revisit Bornu. But his plans were frustrated in consequence of a war which Bello was then waging with the scheik of Bornu, to whom Clapperton bore considerable presents from the king of England. While he was detained by bad health at Sackatoo, the sultan deceiving Lander persuaded him to join his master with the baggage; and on his arrival the intended presents were immediately seized, and the travellers prohibited from proceeding farther.

For some months Clapperton enjoyed tolerable health, but on 13th March 1827, having been suddenly attacked with dysentery, he lingered on till the 13th April, when he expired in the arms of his faithful servant.

Although Clapperton failed in the main object of his ambition, which was afterwards accomplished by Lander, he contributed materially to the advancement of our geographical knowledge of northern Africa. (See Africa.) On the return of Lander to England he published a work entitled "Records of Captain Clapperton's last Expedition to Africa," which appeared in 1830, in 2 vols. 12mo.

CLARE, a maritime county in the north of Munster, Ireland, is bounded N. by the bay and county of Galway, E. by Lough Derg and the river Shannon, which separate it from Tipperary, S. by the estuary of the Shannon, and W. by the Atlantic Ocean. Area, by ordnance survey, 1294 square miles, or 827,994 acres; of which 455,009 are arable, 296,033 uncultivated, 8304 in plantations, 728 in towns, and 67,920 under water.

This county presents great diversity of surface. The barony of Tulla is in part mountainous and moory, intersected in the east and south by a range of hills. Bunratty also contains much rocky ground with good herbage; and towards the southern portion of the barony, adjoining the rivers Fergus and Shannon, some of the level rich land called corcasses, strongly contrasting with the bog, marsh, and rocky pasture prevailing throughout the main portion of the

county. Inchiquin has some beautiful tracts of pasture land with moory hills, and in the eastern portion a calcareous rocky and light soil. Clonderlaw is much encumbered with moor and mountain, but capable of improvement by the application of lime, which is easily procurable. The baronies of Ibrickan, Moyferta, Islanas, and Corcomroe are also within reach of the means of improvement, and in some parts stand much in need of them. Burren produces a short sweet herbage, fit for sheep of middling size and short wool; but it is extremely rocky, the entire surface of the central portion of the barony appearing as one unbroken mass of mountain limestone resembling some of the neighbouring portion of the adjoining county of Galway, of which Oliver Cromwell characteristically remarked that it had not sufficient wood to hang a man, water to drown him, or earth to bury him.

Although the surface of the county is hilly, and in some parts even mountainous, it nowhere rises to a great elevation. Much of the western baronies of Moyarta and Ibrickan is composed of bog land. Bogs are frequent also in the mountainous districts elsewhere, except in the limestone barony of Burren, the inhabitants of some parts of which supply themselves with turf from the opposite shores of Connemara. Generally speaking, the eastern parts of the county are mountainous, with tracts of rich pasture land interspersed; the west abounds with bog; and the north is rocky and best adapted for grazing sheep. In the southern part, along the banks of the Fergus and Shannon, are the bands of rich low grounds called corcasses, of various breadth, indenting the land in a great variety of shapes. They are composed of deep rich loam, and are distinguished as the black corcasses, adapted for tillage, and the blue, used more advantageously as meadow land.

The coast is in general rocky, and occasionally bold and precipitous in the extreme, as may be observed at the picturesque cliffs of Moher within a few miles of Ennistymon, which rise perpendicularly at O'Brien's tower to an elevation of 580 feet. The coast of Clare is indented with several bays, the chief of which are Ballyvaghan, Liscannor, and Malbay; but from Black Head to Loop Head, including the entire western boundary of the county by the Atlantic, there is no safe harbour for a vessel except Liscannor Bay. The county possesses only one large river, the Fergus; but nearly 100 miles of its boundary line are washed by the river Shannon, which, after almost dividing Ireland from north to south, and dispensing its bounties to the adjoining counties of Roscommon, Leitrim, Longford, Westmeath, Galway, King's County, Kerry, Tipperary, and Limerick, enters the Atlantic Ocean between this county and Kerry. The numerous bays and creeks on both sides of this noble river render its navigation safe in every wind; but the passage to and from Limerick is often tedious, and the port of Kilrush may reasonably be expected at some future period to rise in importance under favourable circumstances. The river Fergus is navigable from the Shannon to the town of Clare, which is the terminating point of its natural navigation, the port of all the central districts of the county, and which ought to have been the county town. There are no canals in the county; but a railway from Limerick to Ennis, a distance of 26½ miles, is in progress.

There are upwards of one hundred lakes and tarns in the county, of which the largest are Loughs O'Grady, Graneg, Tedane, Inchiquin, Inniscronan, and Clonlea; but they are more remarkable for picturesque beauty than size or utility, with the exception of the extensive and navigable Lough Derg, formed by the river Shannon between this county and Tipperary. Lough Derg is the largest lake in the whole tract of the Shannon, and one of the finest in Ireland. Besides the perennial lakes, there are many temporary or periodical accumulations of water either forced upwards from under ground of a higher level, or produced by surface water draining down from more elevated spots These dry up in summer, and are called turloghs or loghans On the subsiding of the water, its place is supplied by a copious growth of fine grass, affording pasturage to numerous flocks and herds. These turloghs admit of easy drainage.

Although mineral and metallic substances have been found in many places throughout the county, they do not often show themselves in sufficient abundance to induce the application of capital for their extraction. The principal are lead, iron, and manganese. Lead mines are worked at Kilbricken in the barony of Bunratty (about six miles from Ennis), and at Annaglough. The Milltown lead mine in the barony of Tulla is probably one of the oldest mines in Ireland, and at one time, if the extent of the ancient excavations may be taken as a guide, there must have been a very rich deposit. The richest lead mine in Clare now is the Ballyhickey mine, about 2 miles from Kilbricken. Copper pyrites occurs in several parts of Burren, but in small quantity. Coal has been discovered, but the seams are too thin to warrant the expectation of profit from their being wrought. Limestone occupies all the central and northern parts of the county in a tract bounded on the S. by the Shannon, on the E. by a line running parallel with the Ougarnee river to Scariff Bay, on the N. by the mountain of Talla and the confines of Galway, on the W. by Galway Bay and a line including Kilfenora, Corofin, and Ennis, and meeting the Shannon at the mouth of the Fergus. Within half a mile of the Milltown lead mine are immense natural vaulted passages of limestone, through which the river Ardsullas winds a singular course; and in the grounds of Kiltannon, the residence of James Molony, Esq., the Affic rivulet, one of the numerous tributaries of the Fergus, "dips beneath the surface, and flows for a considerable distance through the caverned limestone; and along its margin paths have been formed to show the limpid water and the singularly fantastic rock—sufficient light being admitted through the natural chinks and apertures of the cavern." The lower limestone of the eastern portion of the county has been found to contain several very large deposits of argentiferous galena. Flags, easily quarried, and raised in blocks or slabs of considerable size, are procured near Kilrush. Thin flags, used for covering houses, are raised near Ennistymon; as are slates for the same purpose in several places, the best being those of Broadford and Killaloe, which are nearly equal to the finest procured in Wales. A species of very fine black marble has been discovered near Ennis; it takes a high polish, and is free from the white spots with which the black Kilkenny marble is marked.

The mineral springs, which are found in many places, are chiefly chalybeate. That of Lisdownvarna, about 8 miles from Ennistymon, has long been celebrated for its medicinal qualities, particularly in biliary obstructions: it is ferruginous, with an astringent taste, and a strong yet not fetid smell. It possesses the additional advantage of being contiguous to the sea, thus affording the valetudinarian the option of sea-bathing if deemed advisable. There are chalybeate springs of less note at Scool, Cloneen, Kilkishen, Burren, Kilcoran, Broadford, Lahinch, Kilkee, Kilrush, Killadysart, and Cassino, near Miltown Malbay. Springs called by the people "holy" or "blessed" wells, generally mineral waters, are common; but the belief in their power of performing cures in inveterate maladies is nearly extinct.

The Atlantic Ocean and the estuary of the Shannon afford many situations admirably adapted for summer bathing places. Among the best frequented of these localities are Burren, Miltown Malbay, one of the best beaches on the western coast, Lahinch, about 2 miles from Ennistymon, and near the interesting cliffs of Moher, with a magnificent and unrivalled beach, on Liscannor Bay, exposed to the full sweep of the western blast, but a delightful summer resi-

dence; also Kilkee, the most fashionable resort for sea bathing on all the western coast of Ireland, and Kilrush on the Shannon estuary.

The climate is healthy. The strong gales from the Atlantic, though unfriendly to planting, insomuch that trees sixty miles inland, if not sheltered, incline towards the east, seem to produce no injurious effects on the human constitution. Yet low fevers are common, and often pass through whole parishes, cutting off numbers. Their frequency and malignity are attributed more to the slovenly habits and want of cleanliness too prevalent among the peasantry, than to any insalubrity in the climate. The use of ardent spirits and insufficient drainage of the land also contribute their baleful agency to increase the extent and virulence of these epidemics; but there is little reason to doubt that were these causes removed, the fevers which have been banished from the fens of Lincolnshire might also be expelled from the county of Clare.

The greater portion of Ireland is bare of wood, but in no part of the country is this barrenness more extreme and apparent. Many square miles present themselves to the view with scarcely the vestige of a tree to vary the monotony of the scene. Many tracts, however, now bare of timber, and affording but a scanty herbage for sheep, and which were once covered with woods, would again be clothed with abundant and profitable wood if properly nurtured and protected from the invasion of sheep and goats. At present plantations are mainly confined to the demesnes and ornamental grounds of the gentry.

The county of Clare which is divided into 11 baronies contains 80 parishes, and includes the diocese of Kilfenora, the greater part of Killaloe, and a very small portion of the diocese of Limerick. It is within the military district of Limerick, with barracks for infantry at Clare Castle, Ennis, Killaloe, and Kilrush; for artillery, in the forts at Scattery Island, Donnaha, Kilcredano, Blackwater, and Kilkerrin. The constabulary force consists of 399 men and officers, with headquarters at Ennis; and nine districts comprise 56 stations at Ennis, Kilrush, Corofin, Killaloe, Ennistymon, Killadysart, Tulla, Newmarket, and Broadford. There are also four revenue police stations, and nine coast-guard stations in the county. The assizes are held at Ennis, where the county prison, the county infirmary, and the district lunatic asylum, are situated. The only savings-bank in the county is at Ennis. There are eight poor-law unions, most of them unfortunately distinguished as having been among the most distressed unions in Ireland.

The amount of property in the county valued under the act 6th and 7th Will. IV., cap. 84 (Griffith's valuation), is L.313,801, and the net annual value of property rated to the poor in the county is L.209,656;—the difference in these valuations having probably arisen from a desire to make the poundage of the rates for the relief of the poor appear excessive, with the object of obtaining more assistance from the fund raised in the more prosperous districts of Ireland, under the name of a rate in aid of distressed unions. The chief towns are Ennis, the county town, situated at the junction of the Clareen and the Fergus, with a population in 1851 of 8623; Kilrush, population 4471; Ennistymon, population 1741; and the ancient and thriving little town of Killaloe, the headquarters of the Inland Steam Navigation Company, with a population of 2230. The county returns three members to the imperial parliament—two for the county at large, constituency under 13th and 14th Vict., cap. 69, in 1853, 3144—and one for the borough of Ennis, constituency 149.

By Ptolemy the inhabitants of this neighbourhood are called Gangani, and are supposed to have been descended from the Concani of Spain.

This county, together with some of the neighbouring district, was anciently called Thomond or Tuadmuin, that is North Munster, and formed part of the monarchy of the celebrated Brian Boroihme, who held his court at Kincora near Killaloe, where his palace was situated on the banks of the Shannon. The site is still distinguished by extensive earthern ramparts. Settlements were effected by the Danes; and in the thirteenth century by the Anglo-Normans, but without permanently affecting the possession of the district by its native proprietors. In 1543 Murrogh O'Brien, after dispossessing his nephew, and vainly attempting a rebellion against the English rule, proceeded to England, and submitted to Henry VIII., resigning his name and possessions. He soon received them back by an English tenure, together with the title of Earl of Thomond, on condition of adopting the English dress, manners, and customs, and maintaining no kerns or gallowglasses. In 1565 this part of Thomond (sometimes called O'Brien's country) was added to Connaught, and made one of the six new counties into which that province was divided by Sir Henry Sidney under the act 11th Elizabeth, cap. 9. It was then named Clare, probably from the name of an English adventurer Thomas de Clare, who obtained a grant from Henry III. of all the lands he should conquer from the Irish, and whose family for some time maintained a precarious position in the district. In 1602 the county was re-annexed to Munster. The O'Briens and other native chieftains had many fierce contests to preserve their independence against the Anglo-Norman and English adventurers, and generally succeeded in maintaining their position as native kings and chieftains of Thomond. From some cause or other the comparative immunity of Clare in ancient times from foreign rule and settlement, and from absenteeism, has proved of doubtful advantage to its modern condition, which has until lately been characterized by extreme social disorganization frequently exhibited in systematic agrarian outrage. The chief ancient families of note in the district were the O'Briens, now represented by the Marquess of Thomond and the O'Briens of Dromoland, of which family are Sir Lucius O'Brien, Bart., who is a lineal descendant of the famous Brian Boroihme; the Macnamaras, now represented by Major Macnamara, formerly M.P. for the county; and the O'Loghlens, of which family is Sir Colman O'Loghlen, Bart.

The county abounds with remains of antiquities, both military and ecclesiastical. Of the former there were lately visible 119 fortified castles, seven of which were inhabited. They are mostly of small extent, a large portion being fortified dwellings. The chief of them is Bunvatty Castle, built in 1277. Raths or Danish forts are to be found in every part. They are generally circular, composed either of large stones without mortar, or of earth thrown up and surrounded by one or more ditches. The list of abbeys and other religious houses formerly flourishing here (some now only known by name, but many of which survive in ruins) comprehends upwards of twenty. The most remarkable are—Quin, said to be one of the finest and most perfect specimens of ancient monastic architecture in Ireland; Corcomroe; Ennis, in which is a very fine window of uncommonly elegant workmanship; and those on Inniscattery, or Scattery Island in the Shannon, said to have been founded by St Senanus. In the island on which, according to tradition, in the time of St Senan, and before the arrival of the Danes, no woman was permitted to land, is a round tower, and the ruins of what are called the seven churches: it is called Holy Island, and is still much frequented by pilgrims. St Senan is often called Saint Shannon; and the boatmen of the neighbourhood reluctantly venture on the management of a vessel which had not made a pilgrimage round his "Sainted Isle," or had not a stone in her keel from the holy strand to keep her from sinking. Scattery Island is one of the most popular burial places in the county, but as it is difficult of access in stormy weather, burials take place at Shanahill near Kilrush, in the belief that all bodies buried at this latter place are miraculously conveyed under the bed of the river into the holy

Clare.

ground of Inniscattery. Kohl remarks that there is no other country in Europe where there are such interesting cemeteries as in Ireland, partly on account of the abundance of ivy, and partly on account of the practice that still prevails of burying the dead among ruins. Four other round towers are to be found in various stages of preservation—at Drumcliffe, Dysert, Kilnby, and Inniscaltra. The cathedral of the diocese of Killaloe, at the town of that name, is a plain massive building originally erected in 1160; and near it are the ruins of the mausoleum of Brian Boroihme. Cromlechs are found chiefly in the limestone rocky district of Burren, though there are some in other baronies. That at Ballygannor is formed of a stone forty feet long and ten broad. The celebrated tomb of Conan, on Mount Callan, is still extant.

Although the soil and surface of the country is in general better adapted for grazing than tillage, yet in the richer lands the latter is extensively carried on. Spade culture is still practised in some parts, and little attention is given to the proper rotation of crops. Husbandry, however, is improving, and will improve in proportion as the prejudices and corruption of former times decline. The diminution in the numbers of the population, and the establishment of a system of poor law, will facilitate and force on both industrial and social amelioration in this district.

In the year 1847 the number of farms or holdings, according to the agricultural returns, was 32,133; which number had declined in 1852 to 16,832. This diminution in the number of farms had been accompanied by a decreased growth of wheat, the ground under that crop in 1847 being 24,308 acres, whilst in 1853 only 7445 acres of wheat were cultivated. The cultivation of potatoes has increased in the same period from 6129 to 31,240 acres. The total extent of land under crops in 1853 was 165,384, viz., wheat 7445, oats 43,382, barley, beans, pease, &c., 18,748, potatoes 31,240, turnips 9664; other green crops 3045; flax, 1007, meadow and clover 50,853. The live stock of the county in 1853 numbered 14,235 horses, 8602 mules and asses, 124,089 cattle, 102,145 sheep, 40,155 pigs, 13,985 goats, and 254,612 poultry, of the total value of L.1,108,954. The live stock of this county in 1849 was valued at L.822,747. Dairies were formerly more numerous than at present, when simple grazing is found more profitable. It cannot be said that there are any manufactures in the county of Clare, although flannels and friezes are made for home use. Hosiery of various kinds, chiefly coarse and strong, is made around Corofin, Ennistymon, and other places; but at present no particular manufacture is attempted on a large scale.

The fishery districts of Kilrush and Seafield extend from Limerick to Blackhead, and comprise 193 miles of maritime boundaries, which in 1853 had 217 registered fishing vessels, employing 1057 men and boys; and the inhabitants of Burren share in the rich fisheries of Galway Bay. The Shannon west of Scattery Island, and the sea along the coasts, are good fishing stations, abounding with cod, haddock, ling, soles, turbot, ray, mackerel, and other fish; but the rugged nature of the coast and the tempestuous sea render this district of comparatively small value for the purposes of navigation and commerce. Near Pooldoody is the great Burren oyster bed, called the Red Bank, where a large establishment is maintained, and from which a constant supply of the excellent Red Bank oysters is furnished to the Dublin and other large markets. Crabs and lobsters are caught in great plenty on the shores of the bay of Galway in every creek from Blackhead to Ardfry. The salmon fishery of the Shannon is very considerable, and eels form another important article of consumption; they abound in every rivulet, and the eel weirs have been charged with being mainly instrumental in causing great damage to the neighbouring lands by obstructing the passage of the waters of the streams.

In 1852 the number of children on the rolls of the national schools for the six months ending the 31st March, was 16,839; of which number 16,654 were Roman Catholics, 125 belonged to the Established church, and the religion of the remainder (60) was not stated in the return.

Clare ‖ Clarification.

According to the latest returns, the state of instruction among the population above the age of five years in the county of Clare, was as follows:—

	Rural Districts.	Civic Districts.	Total.	Proportion per cent. in 1851.	Proportion per cent. in 1841.
Could read and write	17,339	2387	19,726	20	14
Could read only	12,699	1088	13,787	14	14
Could neither read nor write	61,819	4309	66,128	66	72

The population of the county at different periods has been ascertained to be—

Year.	No.	Increase.	Decrease.
1821	208,089	..	...
1831	258,322	50,233	...
1841	286,394	28,072	...
1851	212,428	.	73,966

The decrease of the population is supposed to have taken place in the five years preceding 1851, during which period 25 per cent. of the population of Clare was destroyed by famine and consequent pestilence, or removed by emigration. (H. S—R.)

Clare, or Claremorris, a market-town of Ireland, county of Mayo, 15 miles S.E. of Castlebar. It is neat and well built; and has a court-house, church, 2 chapels, dispensary, union work-house, and an active retail trade. Pop. (1851) 2062, including 500 in workhouse.

Clare Island. See Mayo.

CLARENCIEUX, the second king at arms. See Herald.

CLARENDON, Constitutions of, certain declaratory ordinances made in the reign of Henry II., in a parliament held at Clarendon in Wiltshire, A.D. 1164, by which the power of the pope and his clergy was checked, and the total exemption they claimed from secular jurisdiction greatly narrowed.—(Howell's *State Trials*, vol. ii. p. 546.)

Clarendon, *Earl of.* See Hyde.

CLARET. See Wine-making.

CLARI, Giovanni Carlo Maria, chapel-master at Pistoja, was born at Pisa in 1669. The time of his death is unknown. He was the most celebrated pupil of Colonna, chapel-master of S. Petronio, at Bologna. (See Colonna.) The works by which Clari distinguished himself pre-eminently are his vocal duets and trios, with a continued bass, published in 1720. In these beautiful and learned compositions, the tonal responses and modulations are in the modern style. An edition of these duets and trios, with a pianoforte accompaniment, was published at Paris in 1823, by Mirecki, a Polish musician, and pupil of Cherubini. In such esteem were these compositions held by Cherubini, that, in the course of his studies, he had repeatedly transcribed them with his own hand, as models of excellence. Clari composed one Opera, *Il Savio Delirante;* and for the church, a *Stabat,* and four other works. (G. F. G.)

CLARICHORD, or Clavichord, an old musical instrument of the spinet kind.

CLARIFICATION, the act of clearing; particularly the clearing or fining of liquids from feculent matter by the separation of the insoluble particles. This is performed by depuration, filtration, or coagulation.

The substances usually employed for clarifying liquors are the albumen of eggs, blood, and isinglass. The first two are used for such liquors as are clarified whilst boiling hot; the last for those which are clarified in the cold state, such as wines, &c. The whites of eggs are beaten up into a froth and mixed with the liquor, when they unite with and entangle the impure matters that float in it; and, presently

coagulating by the heat, carry these impurities up to the surface in the form of scum. Blood operates in the same manner. Isinglass is much employed for fining wines. For this purpose, about a quarter of an ounce may be thrown into the cask; or the isinglass may be previously dissolved and boiled down to a slimy consistence. It is then mixed with the liquor by rolling the cask about; after which it is allowed to settle.

CLARIGATIO, in *Roman Antiquity*, a ceremony observed in the proclamation of war. Four heralds being chosen from among the fetiales (a college of priests who acted as guardians of the public faith), one of their number was deputed to act as their representative. This individual, who was styled *pater patratus*, was crowned with the sacred herbs, and sent to the confines of the hostile state; and there, having called the gods to witness that his complaints were just, he demanded redress for the injury sustained. If the offending state failed to comply with his demands within the period stipulated, which was usually thirty or thirty-three days, the herald again proceeded to their frontiers; and hurling a bloody spear within their confines, pronounced a solemn declaration of war. In after times, when war was declared against a distant nation, this ceremony was performed in a field designated Ager Hostilis, near Rome.

CLARINET. See Music, § *Musical Instruments*, and *Appendix* to Music.

CLARION, a small kind of trumpet.

CLARISSES, an order of nuns, so called from their founder St Clara. She was born at Assisi in Italy; and having dedicated herself to religion, founded this order in the year 1212. It comprehends not only those nuns who follow the rule of St Francis to the letter, but likewise those who observe the same rule as modified by several popes. After the conquest of Mexico by Fernando Cortez, Isabella of Portugal, wife of the emperor Charles V. sent thither some nuns of this order, who founded communities of Indian young women, and instructed them in religion, and in such accomplishments as were suitable to their sex. These communities were very considerable—usually consisting of 400 or 500 individuals.

CLARKE, Adam, LL.D., a learned scholar and biblical critic, born of humble parents in 1762, and bred up as a minister among the Wesleyan Methodists. His early education was very limited; but by perseverance and industry he surmounted all obstacles, and became remarkable for the variety and extent of his literary acquirements, on which account he received from the university of St Andrews first the degree of M.A., and afterwards that of LL.D. In 1802 he published an excellent Bibliographical Dictionary in six vols., by which he acquired much reputation. He was then selected by the Record Commission to be the editor of *Rymer's Fœdera*. But his great work, to which all his studies had been more or less preparatory, was his English version of the Holy Scriptures—which excited much attention from the novelty of some of the opinions he entertained, especially as to the fall of our first parents. The first volume appeared in 1810; the eighth and last in 1826. Dr Clarke fell a victim to the Asiatic cholera in 1832.

Clarke, *Edward Daniel*, a celebrated traveller and philosopher, was born at Willingdon, Sussex, June 5, 1769. He received his education at Uckfield, and at the grammar-school of Tunbridge; but he does not appear to have made very satisfactory progress. In 1786 he obtained the office of chapel clerk at Jesus College, Cambridge, but the loss of his father at this time involved him in many difficulties. In 1790 he took his degree, and soon after became private tutor to the Honourable Henry Tufton, nephew to the Duke of Dorset. In 1792 he obtained an engagement to travel with Lord Berwick, through Germany, Switzerland, and Italy; and was thus fortunately enabled to gratify that passion for travelling which had long predominated in his mind over every other. After crossing the Alps and visiting a few of the principal cities of Italy, including Rome, he repaired to Naples, where he remained nearly two years. During his stay he made several excursions to Vesuvius, in one of which he narrowly escaped the fate of Pliny the Elder, having ascended to the edge of the crater during an eruption.

Mr Clarke finally returned to England in the summer of 1794, having been disappointed in the expectation of undertaking a journey to Egypt and the Holy Land. After unsuccessfully attempting a periodical work, he became tutor in several distinguished families, and studiously kept up the practice of journalizing even during short excursions. In 1799 he set out with Mr Cripps, a gentleman of fortune, on a tour through the continent of Europe. From Cambridge they proceeded direct to Norway and Sweden; thence through Russia and the Crimea to Constantinople, Rhodes, and afterwards to Egypt—where, however, their stay was short, as that country was still in the hands of the French. From Egypt they set out for Palestine; and, after visiting Jerusalem, Nazareth, Bethlehem, and other places of interest, they returned to Aboukir Bay. Subsequent to the capitulation of Alexandria, Mr Clarke was of considerable use in securing for England the statues, sarcophagi, maps, manuscripts, &c., which had been collected by the French savans. Greece was the next country visited by the two friends. From Athens they proceeded by land through ancient Thrace to Constantinople; and, after a short stay in that city, directed their course homewards through Rumelia, Austria, Germany, and France, and arrived in England after an absence of three years and a half.

Clarke, who had now obtained considerable reputation, took up his residence at Cambridge, and there continued chiefly to reside till the day of his death. He received the degree of LL.D. shortly after his return, on account of the valuable donations, including a colossal statue of the Eleusinian Ceres, which he had made to the university. In 1805 he published a "Dissertation on the Sarcophagus in the British Museum," and endeavoured, with much ingenuity, to show that it was the coffin of Alexander the Great; but the deciphering of the hieroglyphics upon it since Dr Clarke's time has proved that it was the soros of a monarch named *Her-necht-hebi* (*Amyrtæus*), of the twenty-eighth dynasty. Towards the end of 1808 Dr Clarke was appointed to the professorship of mineralogy, then first instituted. Nor was his perseverance as a traveller otherwise unrewarded. The MSS. which he had collected in the course of his travels were sold to the Bodleian Library for L.1000; and by the publication of his travels he realized altogether a clear profit of L.6595.

Besides lecturing on mineralogy and discharging his clerical duties, Dr Clarke eagerly prosecuted the study of chemistry, and made several discoveries, principally by means of the gas blow-pipe which he had brought to a high degree of perfection. His health, however, soon began to give way under ardent study and long-continued excitement; and after a short illness he expired at London, March 9, 1821. He was buried in Jesus College, Cambridge, where his fellow-collegians erected a monument to his memory. In all the relations of life Dr Clarke was a most amiable man. The leading qualities of his mind were enthusiasm and benevolence, united with a characteristic capacity of enduring long-continued mental as well as physical exertion. The following are his principal works:—

Testimony of different Authors respecting the Colossal Statue of Ceres placed in the vestibule of the Public Library at Cambridge, 8vo, 1801–1803; *The Tomb of Alexander, a Dissertation on the Sarcophagus brought from Alexandria, and now in the British Museum*, 4to, 1805; *A Methodical Distribution of the Mineral Kingdom*, fol., 1807; *A Letter to the Gentlemen of the British Museum*, 4to, 1807; *A Description of the Greek Marbles brought from the shores of the Euxine, Archipelago, and Mediterranean, and deposited in the vestibule of the University Library, Cambridge*, 8vo, 1809; *Travels in various Countries of Europe, Asia, and Africa—Part I., containing Russia, Tar-*

tary, and Turkey, 4to, 1810—*Part II., containing Greece, Egypt, and the Holy Land*, section first, 4to, 1812; section second, 1814. the last volume was published in 1819 In this year also appeared his octavo volume on the Gas Blow-pipe; and in the year following a Dissertation on the Litnus. Besides these works, Dr Clarke wrote a number of articles for scientific journals.

CLARKE, *Dr Samuel* (1599-1682), a preacher and writer of considerable note in the reign of Charles II. was, during the interregnum, and at the time of the ejection, minister of St Dennet Fink, in London. In November 1660, he, in the name of the Presbyterian ministers, presented an address to the king for his declaration of liberty of conscience; and he was also one of the commissioners of the Savoy. He was the author of *A Looking-Glass for Saints and Sinners; The Marrow of Ecclesiastical History; A General Martyrology;* and the *Marrow of Divinity.*

CLARKE, *Samuel*, the son of the former, was fellow of Pembroke-hall, Cambridge, but was ejected from his fellowship and his living during the commonwealth for refusing to take the oaths. He was the author of *Annotations on the Bible*, and died in 1701.

CLARKE, *Dr Samuel*, a celebrated English philosopher and divine, was the son of Mr Edward Clarke, alderman of Norwich, and who had represented that city in parliament for several years. He was born October 11, 1675; and having finished his education at the free school of Norwich in 1691, removed thence to Caius College, Cambridge, where his uncommon abilities soon began to display themselves. Though the philosophy of Descartes was at that time the reigning system at the university, yet Clarke easily mastered the new system of Newton, and contributed greatly to the spread of the Newtonian philosophy by publishing an excellent translation of Rohault's *Physics* with notes, which he finished before he was twenty-two years of age. The system of Rohault was founded entirely upon Cartesian principles, and was previously known only through the medium of a rude Latin version. Clarke not only gave a new translation, but added to it such notes as were calculated to lead students insensibly to other and truer notions of science. "The success," says Bishop Hoadley, "answered exceedingly well to his hopes; and he may justly be styled a great benefactor to the university in this attempt." It continued to be used as a text-book in the university till supplanted by the treatises of Newton, which it had been designed to introduce. Whiston relates that, in 1697, he met young Clarke (at that time chaplain to Moore, bishop of Norwich), then wholly unknown to him, at a coffeehouse in that city, where they entered into conversation about the Cartesian philosophy, particularly Rohault's *Physics*, which Clarke's tutor, as he tells us, had put him upon translating. "The result of this conversation was," says Whiston, "that I was greatly surprised that so young a man as Clarke then was should know so much of those sublime discoveries, which were then almost a secret to all but to a few particular mathematicians. Nor do I remember," continues he, "above one or two at the most, whom I had then met with, that seemed to know so much of that philosophy as Clarke." This translation of Rohault was first printed in 1697, 8vo. There have been four editions of it: the last and best is that of 1718, which has the following title: *JACOBI ROHAULTI Physica. Latine vertit, recensuit, et uberioribus jam Annotationibus, ex illustrissimi Isaaci Newtoni Philosophia maximam partem haustis, amplificavit et ornavit S. Clarke, S. T. P. Accedunt etiam in hac quarta editione novæ aliquot tabulæ æri incisæ et Annotationes multum sunt auctæ.* It was translated into English by Dr John Clarke, dean of Sarum, and published in two vols. 8vo.

Clarke afterwards turned his thoughts to divinity; and in order to qualify himself for the sacred office, devoted himself to the study of Scripture in the original, and of the primitive Christian writers. Having taken holy orders, he became chaplain to Moore, bishop of Norwich, who was ever afterwards his constant friend and patron. In 1699 he published two treatises; one entitled "Three practical Essays on Baptism, Confirmation, and Repentance;" and the other, "Some Reflections on that part of a book called Amyntor, or a Defence of Milton's Life, which relates to the Writings of the Primitive Fathers, and the Canon of the New Testament." In 1701 he published "A Paraphrase upon the Gospel of St Matthew;" which was followed, in 1702, by the "Paraphrases upon the Gospels of St Mark and St Luke," and soon afterwards by a third volume upon St John. They were subsequently printed together in two volumes 8vo; and have since passed through several editions. He intended to have treated in the same manner the remaining books of the New Testament, but something accidentally interrupted the execution of his design.

Meanwhile Bishop Moore gave him the rectory of Drayton, near Norwich, and procured him a parish in the city. In 1704 he was appointed to the Boyle lectureship, and chose for his subject the Being and Attributes of God. Having been appointed to the same office in the following year, he chose for his subject the Evidences of Natural and Revealed Religion. These lectures were first printed in two distinct volumes; but were afterwards collected together, and published under the general title of "A Discourse concerning the Being and Attributes of God, the Obligations of Natural Religion, and the Truth and Certainty of the Christian Revelation, in opposition to Hobbes, Spinoza, the author of the Oracles of Reason, and other Deniers of Natural and Revealed Religion." (For an account of Clarke's famous argument, and his metaphysical speculation generally, see DISSERTATION I., vol. i., pp. 139-151; and in an ethical point of view, see DISSERTATION II., vol. i., pp. 343-347.)

In 1706 he wrote a refutation of some positions which had been maintained by Dr Dodwell on the immortality of the soul; and this drew him into the controversy with Collins, of which an account is given in the same DISSERTATION. He also at this time wrote a translation of Newton's Optics, for which the author presented him with L.500. In the same year also, through the influence of Bishop Moore, he procured for him the rectory of St Bennet's, Paul's Wharf, London; and soon afterwards appeared at the court of Queen Anne, who appointed him one of her chaplains in ordinary; and afterwards, in 1709, presented him to the rectory of St James's, Westminster. On his elevation to this latter office, he took the degree of doctor in divinity, defending as his thesis the two questions: 1. *Nullum fidei Christianæ dogma, in Sacris Scripturis traditum, est rectæ rationi dissentaneum;* no article of the Christain faith, delivered in the Holy Scriptures, is disagreeable to right reason: 2. *Sine actionum humanarum libertate nulla potest esse religio;* without the liberty of human actions, there can be no religion. During the same year, at the request of the author, he revised and corrected Whiston's English translation of the Apostolical Constitutions.

In 1712 he published a carefully punctuated and annotated edition of Cæsar's Commentaries, adorned with elegant engravings. It was printed in folio, 1712, and afterwards in 8vo, 1720, and dedicated to the Duke of Marlborough. During the same year he published his celebrated treatise on *The Scripture Doctrine of the Trinity.* It is divided into three parts. The first contains a collection and exegesis of all the texts in the New Testament relating to the doctrine of the trinity; in the second the doctrine is set forth at large, and explained in particular and distinct propositions; and in the third, the principal passages in the liturgy of the Church of England relating to the doctrine of the trinity are considered. Whiston informs us, that some time before the publication of this book, a message was sent to him from Lord Godolphin and

other ministers of Queen Anne, importing "That the affairs of the public were with difficulty then kept in the hands of those that were for liberty; that it was therefore an unseasonable time for the publication of a book that would make a great noise and disturbance; and that therefore they desired him to forbear till a fitter opportunity should offer itself," a message that Clarke of course entirely disregarded. The ministers were right in their conjectures; and the work not only provoked a great number of replies, but occasioned a formal complaint from the lower house of convocation. Clarke, in reply, drew up an apologetic preface, and afterwards gave several explanations, which satisfied the upper house; and having pledged himself that his future conduct would occasion no trouble, the matter dropped.

In 1715 and 1716, he had a discussion with Leibnitz relative to the principles of natural philosophy and religion, which was at length cut short by the death of his antagonist. A collection of the papers which passed between them was published in 1717. In 1719 he was presented by Lord Lechmere to the mastership of Wigston's hospital in Leicester. In 1724 he published seventeen sermons, eleven of which had not before been printed. In 1727, upon the death of Sir Isaac Newton, he was offered by the court the place of Master of the Mint, worth on an average from L.1200 to L.1500 a year. This secular preferment, however, he absolutely refused,—a circumstance which Whiston regards as "one of the most glorious actions of his life, and affording undeniable conviction that he was in earnest in his religion." In 1728 was published "A Letter from Dr Clarke to Benjamin Hoadley, F.R.S., occasioned by the controversy relating to the Proportion of Velocity and Force in Bodies in Motion;" printed in the Philosophical Transactions. In 1729 he published the first twelve books of Homer's Iliad. This edition was printed in quarto, and dedicated to the Duke of Cumberland. "The translation of Homer, who was Clarke's favourite author," says Bishop Hoadley, "with his corrections, may now be styled accurate; and his notes, as far as they go, are indeed a treasury of grammatical and critical knowledge. He was called to his task by royal command, and he has performed it in such a manner as to be worthy of the young prince for whom it was laboured." The year of its publication was the last of Clarke's life. Hitherto, though not robust, he had always enjoyed a firm state of health; but on the morning of Sunday, 11th May 1729, when going out to preach before the judges at Sergeant's Inn, he was seized with a sudden illness, which caused his death on the Saturday morning following. He died, May 17, 1729, in the 54th year of his age.

Soon after his death were published, from his original manuscripts, by his brother Dr John Clarke, dean of Sarum, *An Exposition of the Church Catechism*, and ten volumes of sermons, in 8vo. His *Exposition* is composed of those lectures which he read every Thursday morning, for some months in the year, at St James's church. In the latter part of his life he revised them with great care, and left them completely prepared for the press. Three years after his death appeared also the last twelve books of the Iliad, published in 4to by his son Mr Samuel Clarke; who informs us in the preface, that his father had finished the annotations to the first three of these books, and as far as the 359th verse of the fourth; and had revised the text and version as far as verse 510 of the same book.

Dr Clarke was of a cheerful and even playful disposition. An intimate friend of his, the Reverend Mr Bott, used to relate, that once when he happened to call for him he found him swimming upon a table. At another time, when the two Drs Clarke, Mr Bott, and several men of ability and learning were together, and amusing themselves with diverting tricks, Dr Samuel Clarke, looking out at the window, saw a grave blockhead approaching the house; upon which he cried out, "Boys, boys, be wise, here comes a fool." This turn of his mind has since been confirmed by Dr Warton, who, in his observations upon the line of Mr Pope,

Unthought-of frailties cheat us in the wise,

says, "Who could imagine that Locke was fond of romances; that Newton once studied astrology; that Dr Clarke valued himself on his agility, and frequently amused himself in a private room of his house in leaping over the tables and chairs; and that our author himself was a great epicure?"

CLARKE, *William* (1696–1771), a learned divine, was born at Haghmon Abbey, Shropshire. He was elected fellow of St John's College, Cambridge, in 1716; and in 1724 was presented by Archbishop Wake to the rectory of Buxted in Sussex. In 1738 he was made prebendary and residentiary of the cathedral church at Chichester. Some years before this he had become known by a preface to Dr Wotton's *Leges Walliæ Ecclesiasticæ et Civiles Hocli Boni, et aliorum, Walliæ Principum;* and he was probably the author of a *Discourse on the Commerce of the Romans*, which was highly extolled by Dr Taylor in his *Elements of the Civil Law*, and is reprinted in Bowyer's *Miscellaneous Tracts*. But Mr Clarke's chief work was, *The Connexion of the Roman, Saxon, and English Coins*, &c., 4to, 1767; and its appearance was owing to the then recent discovery of the old Saxon pound. It was dedicated to the Duke of Newcastle; and in its composition Clarke was chiefly indebted to Bowyer, who took upon him all the care of the publication, drew up several of the notes, and wrote part of the dissertation on the Roman sesterce. Mr Clarke was afterwards promoted to the chancellorship of the church of Chichester, and the vicarage of Amport. In Nichols's Anecdotes of Bowyer there are several letters and extracts of letters written to that learned printer by Mr Clarke, which place his character in a favourable light.

CLARKSON, THOMAS, one of the most zealous labourers for the abolition of the slave-trade, to which object he devoted his life, was the son of a clergyman at Wisbeach, where he was born in 1760. He lived to witness the extinction of the British slave-trade in 1807, and the emancipation of the negroes in 1838. He died at Playford Hall, Suffolk, in 1846. See SLAVERY.

CLARO-OBSCURO, CHIAROSCURO, or CLAIR-OBSCURE, in painting, the art of distributing to advantage the lights and shadows, both with respect to relief, and to general effect. The term is also applied to a design of only two colours, as black and white, or black and yellow; or to a design washed only with one colour, the shadows being brown, and the lights heightened up by white. It is likewise applied sometimes to prints of two colours taken off at twice.

CLASS, a scientific division or arrangement of beings or of things which have something in common, or are ranged under a common denomination. Thus, *animals* are divided into the classes of quadrupeds, birds, fishes, &c., which again are subdivided into orders, and these into genera and species. See ANIMAL KINGDOM, and BOTANY.

CLASSIC, or CLASSICAL, an epithet applied to ancient Greek and Roman authors of the first rank; and thence to such modern authors as are held in the highest estimation. The term seems to owe its origin to Tullius Servius, who, in order to make an estimate of every person's estate, divided the Roman people into six *classes*. The estate of the first class was not to be under L.200, and these by way of eminence were called *classici*, classics; hence authors of the first rank came to be called *classics*, while all the rest were said to be *infra classem*.

CLASSICUM, in *Roman Antiquity*, the alarm given by the sound of trumpet as the signal for battle. Hence also applied to the instrument itself.

CLATHRI, in *Antiquity*, a kind of lattice or trellis-work for securing doors and windows.

CLAUBERG, JOHN (1622-1665), was born at Salingen in the duchy of Berg, and professed philosophy and theology, first at Herborn, and afterwards at Duisburg. He was one of the first who introduced into Germany the Cartesian philosophy, which he had studied under John Ray at Leyden. His philosophical works (*Opera Omnia Philosophica*), collected at Amsterdam by John Theodore Schalbruch, two vols. 4to, with a life of the author by John Christian Hennius, show how thoroughly he appreciated the merits of the French philosopher. The most esteemed of Clauberg's works is his *Logica Vetus et Nova;* but he has not admitted in this collection a little work entitled *Ars Etymologica Teutonum e Philosophiæ fontibus derivata*, published by him at Duisburg in 1663, in 8vo, and which Morhoi has highly commended in his *Polyhistor*, and Leibnitz included in his *Collectanea Etymologica.* This brochure was intended as the prelude to a large work, *De Causis Linguæ Germanicæ*, which, however, the projector did not find leisure or encouragement to execute. In a separate form have been collected *J. Claubergii et Martini Hundii Dissertationes selectæ, quibus controversiæ fidei adversus omnis generis adversarios explicantur*, and *J. Claubergii et Tobiæ Andreæ Exercitationes et Epistolæ varii argumenti.*

CLAUDE, JEAN (1619-1687), an eminent French Protestant divine, was born at Sauvetat near Agen, where his father was a Protestant minister. He held for eight years the office of professor of theology in the Protestant college of Nismes; and after he was compelled to abandon his chair, he still maintained his ground on the field of controversy by his able replies to Bossuet, Arnauld, Nicole, and others. On the revocation of the edict of Nantes he fled to Holland, where he was pensioned by the Prince of Orange. He continued to preach occasionally at the Hague till his death. His principal works are the *Réponse au Traité de la perpétuité de la Foi sur l'Eucharistie*, 2 vols. 8vo; *Défense de la Reformation, ou Réponse aux Préjugés légitimes de Nicole;* and *Plaintes des Protestans cruellement opprimés dans le Royaume de France.*

CLAUDE LORRAINE, or CLAUDE GELÉE (1600-1682), the celebrated landscape painter, was born at the village of Chamaone in Lorraine. When it was discovered that he made no progress at school, he was apprenticed to a pastry-cook. He afterwards rambled to Rome to seek a livelihood; but from his clownishness and ignorance of the language, he failed to obtain permanent employment. Chance threw him at last in the way of Augustin Tassi, a painter, who hired him to grind his colours, and to do all the household drudgery. His master hoping to make him serviceable in some of his greatest works, taught him by degrees the rules of perspective and the elements of design. Under his tuition the mind of Claude began to expand, and he devoted himself to artistic study with great eagerness. He exerted his utmost industry to explore the true principles of painting by an incessant examination of nature; and for this purpose he made his studies in the open fields, where he very frequently remained from sunrise till sunset, watching the effect of the shifting light upon the landscape. He generally sketched whatever he thought beautiful or striking, marking every curious tinge of light with a similar colour; and from these sketches he perfected his landscapes so as to make them true to nature to a degree which has never been surpassed.

Claude was not only acquainted historically with the facts, but also scientifically with the laws of nature; and Sandrart relates that he used to explain to him, as they walked through the fields, the causes of the different appearances of the same landscape at different hours of the day, from the reflections or refractions of light, or from the morning and evening dews or vapours, with all the precision of a philosopher. He elaborated his pictures with great care; and if any performance fell short of his ideas, he altered, erased, and repainted it several times over, till it corresponded with the image pictured in his mind.

His skies are aërial and full of lustre, and every object harmoniously illumined. His distances are admirable, his invention delightful, his colouring delicate, and his tints have an inimitable sweetness and variety. He frequently gave an uncommon tenderness to his finished trees by glazing; and in his large compositions, which he painted in fresco, he was so exact, that the distinct species of every tree might readily be distinguished. His figures, however, are very indifferent; but he was so conscious of his deficiency in this respect, that he usually engaged other artists to paint them for him, among whom were Curtois and Filippo Lauri. In order to avoid a repetition of the same subject, and also to detect spurious copies of his works, he made a tinted outline drawing (in paper-books prepared for this purpose) of the designs of all those pictures which were transmitted to different countries; and on the back of the drawings he wrote the name of the person who had been the purchaser. These books he named *Libri di Verità.* This valuable work has been engraved and published, and is one of the greatest boons ever conferred upon the students of the art of landscape. Claude died at Rome at the age of eighty-two. Many noble specimens of his genius may be seen in the National Gallery, and in the Louvre at Paris.

CLAUDE, ST, a town of France, capital of a cognominal arrondissement, department of Jura, at the confluence of the Bienne and Isson, 28 miles S.E. of Lons-le-Saulnier. Pop. (1851) 5835. It has considerable manufactures of articles in wood, horn, and ivory; and of toys, jewellery, hardware, &c.

CLAUDIA, a Roman matron (not a vestal virgin, as frequently stated), who is said to have cleared herself of the imputation of incontinence in the following manner:—When the image of Cybele was brought out of Phrygia to Rome, the barge in which it was conveyed stuck fast on a bank in the Tiber; whereupon Claudia tied her girdle, the badge of chastity, to the barge, and drew it along to the city,—a feat which a thousand men had been unable to do. (Ovid, *Fast.* iv. 305.)

CLAUDIANUS, CLAUDIUS, a celebrated Latin poet, flourished under the emperor Theodosius and his sons Arcadius and Honorius. It appears from the direct testimony of Suidas that Claudian was a native of Alexandria. He went to Rome in A.D. 395, when he was about twenty years of age, and there he obtained the patronage of Stilicho—a man distinguished alike in the cabinet and the field, and who possessed so much influence under the emperor Honorius that for many years he was the real governor of the Western Empire. Stilicho afterwards fell into disgrace, and was put to death in 408; and it is conjectured that the poet was involved in the misfortunes of his patron. It has also been asserted, though without sufficient evidence, that Claudian suffered severe persecution from his successor Hadrian, an Egyptian by birth, who was captain of the guards to Honorius. However this may be, he was afterwards in high favour, and obtained various honours, as appears from an inscription discovered at Rome in the fifteenth century. Through the interposition, too, of Serena, the wife of Stilicho, he obtained in marriage a lady of high rank and wealth in Libya.

There are a few Christian hymns which, through mistake, have been ascribed by some critics to Claudian; but we have the explicit testimony of his contemporary St Augustin that Claudian was a heathen. The time of his death is uncertain. The style of Claudian is classically pure, and his works bear the impress of true genius. Among the editions may be noticed that of 1765, *cum notis variorum*, 8vo; the Delphin edition of 1677, 4to; that of Gesner, Leipsic, 1759, 2 vols. 8vo; and that of the younger Burmann, Amsterdam, 1760, 4to, which is decidedly the best. There is a com-

plete metrical translation of his whole works by A. H wkins, 2 vols. 8vo, Lond. 1817.

CLAUDIUS I. and II. See ROMAN HISTORY.

CLAUSE, in *Grammar*, a member of a period or sentence. Also an article in a contract, a charge or condition in a testament, &c.

CLAUSENBURG. See KLAUSENBURG.

CLAUSTHAL. See KLAUSTHAL.

CLAVARIUM, an allowance made to the Roman soldiers for the purchase of shoe-nails. In later times they frequently mutinied, demanding largesses of the emperors under this pretence.

CLAVES INSULÆ, a term used in the Isle of Man, where all weighty and ambiguous causes are referred to a jury of twelve, called *claves insulæ*, the keys of the island.

CLAVICHORD, and CLAVICTHERIUM, two musical instruments of the spinet kind, in use in the sixteenth century.

CLAVICLE, the collar bone. See ANATOMY, vol. iii., p. 31.

CLAVICYMBALUM, an old keyed-instrument of the harpsichord kind.

CLAVIUS, CHRISTOPHER (1537–1612), a German Jesuit and mathematician, born at Bamberg. He was employed to rectify the calendar, and undertook a defence of it against Scaliger. His works, in five vols. fol., contain a Commentary on Euclid's *Geometry*, and other elementary treatises.

CLAVUS, in *Antiquity*, a purple stripe on the robes of the Roman senators and knights, which was broad or narrow according to the rank of the wearer. Hence the distinction of tunica angusti-clavia and lati-clavia. See ANGUSTICLAVIA.

CLAVUS *Annalis*. According to a Tuscan custom, the early Romans kept a register of time by means of nails; and hence the term *clavus annalis*. For this purpose there was an ancient law, ordaining the chief magistrate to drive a nail every year on the ides of September into the side wall of the temple of Jupiter Optimus Maximus.

CLAY. See BRICKMAKING, and INDEX.

CLAY, *Henry*, a distinguished American statesman, was born April 12, 1777, in Hanover county, Virginia, where his father was a clergyman. He was educated for the bar; and having been licensed as an attorney in 1797, he removed to Lexington, Kentucky, where his abilities soon procured for him the most honourable distinction. He was elected in 1806, and again in 1810, to fill a vacancy in the United States senate; and was afterwards chosen speaker of the House of Representatives in Washington. In this capacity he warmly advocated the war with Great Britain; and in 1814 he was sent to Ghent as one of the commissioners for negotiating a peace. On his return, he was again elected speaker in congress; and afterwards filled the office of secretary of state during the presidency of Adams. In 1832 he stood as candidate for the presidentship, but was defeated by General Jackson. During the agitation of the tariff question he was the principal means of restoring peace to the country by bringing in the celebrated compromise bill. He resigned his seat in the senate in 1842, was again defeated by the election of President Polk in 1844, and did not resume his place in congress till 1849. In 1851 he gave in his final resignation on account of the state of his health, which rapidly declined till his death in the following year. As a speaker, he was distinguished by the clear and silvery tones of his voice; and though he was never elected president, his ability as a statesman has rendered him worthy of one of the highest places in the annals of his country.

CLAYTON, ROBERT, D.D. (1695–1758), a distinguished prelate and member of the Royal and Antiquarian Societies of London. He was advanced to the bishopric of Killala in 1729, translated to the see of Cork in 1735, and to that of Clogher in 1745. His preferment, in spite of his Arian opinions, was chiefly owing to the influence of his friends at court; but having ventured to propose in the House of Lords that the Nicene and Athanasian creeds should be expunged from the liturgy, a prosecution was ordered against him by the crown. He died, however, on the day fixed for the opening of the trial.

His publications are, 1. *A Letter in the Philosophical Transactions*, No. 461, p. 813, giving an account of a Frenchman seventy years old (at Inishanan, in his diocese of Cork), who said he gave suck to a child; 2. *The Chronology of the Hebrew Bible vindicated*, 1751, 4to; 3. *An impartial Inquiry into the time of the coming of the Messiah*, 1751, 8vo; 4. *An Essay on Spirit*, 1751, 8vo; 5. *A Vindication of the Histories of the Old and New Testaments, in answer to the Objections of Lord Bolingbroke, in two Letters to a young Nobleman*, 1752, 8vo; 6. *A Defence of the Essay on Spirit, with Remarks on the several pretended Answers*, 1753, 8vo; 7. *A Journal from Grand Cairo to Mount Sinai, and back again, translated from a manuscript written by the prefetto of Egypt, in company with some Missionaries* de propaganda fide *at Grand Cairo;* to which are added, *Remarks on the Origin of Hieroglyphics, and the Mythology of the ancient Heathens*, 1753, 8vo; 8. *Some Thoughts on Self-love, Innate Ideas, Free-will, Taste, Sentiments, Liberty and Necessity, occasioned by reading Mr Hume's Works, and the short Treatise written in French by Lord Bolingbroke on Compassion*, 1754, 8vo; 9. *A Vindication of the Histories of the Old and New Testaments*, Part II., adorned with several Explanatory Cuts, 1754, 8vo; 10. *Letters between the Bishop of Clogher and Mr William Penn, concerning Baptism*, 1755, 8vo; 11. *A speech delivered in the House of Lords in Ireland, on Monday, 2d February 1736, for omitting the Nicene and Athanasian Creeds out of the Liturgy*, 1756, 8vo; 12. *A Vindication*, Part III., 1758, 8vo.

CLAZOMENÆ (*Kelisman*), a town of Ionia, and a member of the Ionian Dodecapolis, on the gulf of Smyrna, about 20 miles from that city in a S.W. direction. It stood originally on the isthmus connecting the mainland with the peninsula on which were Erythræ and other towns of note; but the inhabitants, alarmed by the encroachments of the Persians, abandoned the continent and removed to one of the small islands of the bay, and there established their city in security. This island was connected with the mainland by Alexander the Great by means of a pier, the remains of which are still visible. Though Clazomenæ was not in existence before the arrival of the Ionians in Asia, its original founders were only partly Ionians, the great proportion being Phliasians and Cleonæans. It remained for some time subject to the Athenians, but about the middle of the Peloponnesian war it revolted. After a brief resistance, however, it again acknowledged the Athenian supremacy, and repelled the Lacedæmonians when they attempted to gain possession of the town. Under the Romans Clazomenæ was included in the province of Asia, and enjoyed immunity. Anaxagoras the philosopher was born here B.C. 499.

CLEANTHES, a Stoic philosopher, who flourished about B.C. 240. He was originally a boxer; and during the time he studied philosophy under Zeno he worked all night at drawing water for a gardener. When this circumstance became known to the Areiopagus, who had cited him before them to give an account of his somewhat suspicious mode of life, they decreed him a present of ten minæ, which he indignantly refused. From his powers of patient endurance he was known by his fellow-pupils as *the ass;* but so high was their esteem for him, that on the death of Zeno he became his successor in the school. He wrote numerous treatises on topics common to the Stoic philosophers generally.

CLEARCHUS, a tyrant of Heraclea in Pontus, who was killed by Chion and Leonidas, Plato's pupils, during the celebration of the festivals of Bacchus. He had enjoyed the sovereign power for twelve years.

CLEARCHUS was also the name of a Lacedæmonian who was sent to gain over the Byzantines to the Lacedæmonian interest. Being soon afterwards recalled, he refused to obey, and fled to Cyrus the Younger, who made him captain of 13,000 Greeks, whom he had hired to fight against his brother. He obtained a victory over Artaxerxes, who was so enraged at the defeat that when Clearchus fell into his hands by the treachery of Tissaphernes, the king immediately put him to death.

CLEAT, a small piece of wood or iron with either one

or two projecting ends, fixed in different parts of a ship to belay ropes to.

CLECHE, in *Heraldry*, a kind of cross, charged with another cross of the same figure, but of the colour of the field. See HERALDRY.

CLEDGE, among miners, the upper stratum of fullers' earth.

CLEDONISMUS, among the ancient Greeks, a kind of divination drawn from words occasionally uttered. Cicero observes, that the Pythagoreans believed the pronouncing of certain words, for instance *incendium*, during a meal, very unlucky. Thus, instead of prison, they used the word *domicilium;* and to avoid *erinnys*, furies, they said *eumenides*.

CLEF, or CLIFF, in *Music*, a character which, placed at the beginning of a stave, determines the degree of elevation of that stave in the general system, and indicates the names of all the notes which that stave contains. Thus we have the C clef, the F clef, the G clef.

CLEISTHENES, a famous Athenian magistrate, who is said to have instituted ostracism (Ælian, *V. H.* iii. 24). He flourished B.C. 510. See ATTICA.

CLEMENS ROMANUS, bishop of Rome at the end of the first century, and supposed to be the same with the Clement mentioned in Philip. iv. 3. Of his personal history nothing is known. To him are ascribed two epistles, and a work called the *Recognitiones;* but the epistles, if genuine, are interpolated, and the Recognitions are generally regarded as spurious. *The Clementines*, a series of Judaizing homilies, are supposed by Neander to be the work of an Ebionite.

CLEMENS, TITUS FLAVIUS, surnamed *Alexandrinus* because he lived at Alexandria, was born at Athens. His early life was spent partly in the study of philosophy and partly in travelling. Though previously acquainted with the Christian system, he does not seem to have embraced Christianity till he entered the school of Pantænus, to whom he afterwards became assistant. During the reign of Severus he fled to Palestine; and after residing for a short time at Jerusalem and Antioch, it is probable that he returned to Alexandria, where he died about B.C. 220. In his philosophy Clement was an eclectic, and in his interpretation of Scripture he shows much of that fanciful exegesis which received its fuller development in his pupil Origen. Of his works a considerable number still remain. They are principally written with the intent of elevating the Greeks from the condition of heathens to that of perfect Gnostics. In the fifth book of the *Stromata* there is much valuable information on the subject of Egyptian hieroglyphics. The best edition of Clement's works is that of Potter, Oxon. 1715, 2 vols. fol.

CLEMENT V., POPE, a Frenchman, and Archbishop of Bourdeaux, succeeded Benedict XI. in 1305. He transplanted the holy see to Avignon in France, greatly contributed to the suppression of the Templars, and was author of a compilation of the decrees of the general councils of Vienne, styled *Clementines*. He died in 1314.

CLEMENT VII., *Giulio de Medici, Pope*, memorable for his refusal to divorce Catharine of Aragon from Henry VIII.; and for the bull he published upon the king's marriage with Anne Boleyn, which sealed the schism between Rome and England. During his pontificate Rome was stormed and pillaged by the armies of Charles V. Clement died in 1534, and is justly regarded as infamous for his avarice and deceit.

CLEMENT XI., *Gian Francesco Albani*, was elected pope A.D. 1700. He was engaged in hostilities with the Emperor Joseph I., but was defeated and obliged to sue for peace. He was, however, no less tenacious of his temporal prerogatives than of his spiritual power, which he maintained in his bull *Vineam Domini* against the Jansenists, and again in the famous bull *Unigenitus* issued in condemnation of Quesnel's *Reflections on the New Testament*. The latter of these was ultimately recognised by the French king, but tended for a long time to alienate the French from their obedience to the Roman see. Clement espoused the cause of the Pretender, thinking him a fit instrument for regaining England to Catholicism. He also succoured the Venetians against the Turks, who had invaded Corfu, but were compelled to raise the siege. Clement was at once a generous and amiable man, and devoted a large share of his revenue to the embellishment of Rome, and the patronage of literature and art. He died in 1721.

CLEMENT XIV., *Gian Vincenzo Ganganelli*, was born at St Angelo, October 1705, and chosen pope, before he had attained a bishopric, in 1769, when the see of Rome was involved in a violent contest with the foreign powers. His reign was distracted by the contests which then raged in regard to the abolition of the Jesuit order; and Ganganelli has rendered himself famous by issuing a bull for their suppression. His latter days were embittered by apprehensions of poison, which made him frequently regret the loss of that tranquillity which he enjoyed when only a simple Franciscan. He died in 1774, and his death, which was immediately attributed to poison, gave rise to the circulation of the most extravagant reports, which seem to have been countenanced by the foreign powers for the sake of inflaming popular odium against the Jesuits. It was confidently reported that at the *post mortem* examination the head fell off from the body, and that the stench poisoned and killed the operators. The operators, however, showed themselves alive and in good health, and the surgeons and physicians testified to the falsehood of the report. Clement XIV. appears to have been a man of virtuous character, and possessed of considerable abilities. His enlightenment and liberality, however, were little suited to the taste of the age in which he lived. The collection of letters published under his name is not devoid of interest; but it is well known that they were written by Caraccioli, who, however, persisted till his death in asserting that he was only their translator.

CLEMENTI, MUZIO, the composer and pianist, was born at Rome in 1752, and died at London on 10th March 1832. After studying music under various masters at Rome, he was taken to England, when 14 years old, by Mr Peter Beckford, who was so charmed with the boy's skill as a harpsichord-player that he promised to establish him in this country. Under Mr Beckford's roof, in Dorsetshire, Clementi studied music so assiduously that when eighteen years old he had become not only the greatest harpsichord-player of his time, but had published his second work, which originated the new style of sonatas for that instrument. C. P. E. Bach had already opened the new path which Clementi improved and extended. Clementi then went to London, where his constant intercourse with the best Italian singers improved his taste. In 1780 he visited Paris, and next year Vienna, where he became intimately acquainted with Haydn and Mozart. He returned to London in 1783, and revisited France in 1784. Returning to London in 1785, he devoted himself to teaching until 1800, when he entered into a partnership for pianoforte-making and music-selling. In 1803 he went to St Petersburg with his remarkable English pupil John Field. He afterwards travelled in Italy, whence he returned to England in 1810. He was twice married. His works are numerous, and all excellent of their kind. He composed 106 sonatas for the harpsichord and for the pianoforte; a number of other pieces for the pianoforte; a large work, "Gradus ad Parnassum," or the art of pianoforte-playing; several symphonies and overtures; arrangements of Haydn's "Creation" and "Seasons," &c.; and edited three volumes of a *selection of practical harmony for the organ or pianoforte*. Clementi's style of composition is elegant and brilliant, but generally dry and unimpassioned. He stood at the head of the best school of pianists, understanding perfectly the true nature and powers

of his instrument, and taught many eminent pupils, among whom were J. B. Cramer and John Field. (G.F.G.)

CLEMENTINE, a term among the Augustines for a person who, after having been nine years a superior, ceases to be so, and becomes a private monk, in conformity with a bull of Pope Clement.

CLEMENTINES, the constitutions of Pope Clement V. and the canons of the council of Vienne.

CLENARD, or KLEINARTS, NICHOLAS, a celebrated grammarian, was born at Diest, Brabant, in 1495. After having taught humanity at Louvain, where he had studied, he travelled into France, Spain, Portugal, and Africa. He wrote, 1. *Tabula in Grammaticam Hebrœam*, Louvain, 1529, 8vo; 2. *Institutiones Linguœ Grœcœ*, Louvain, 1530, composed with the aid of Rescius; 3. *Meditationes Grœcanicœ*, Louvain, 1531; 4. *Epistolarum Libri duo*, Louvain, 1550, 8vo. Clenard died at Granada in 1542.

CLEOBIS and BITON, the sons of Cydippe, a priestess of Hera (Juno) at Argos. When oxen could not be procured for their mother's chariot, they put themselves under the yoke, and drew it 45 stadia to the temple, amidst the acclamations of the multitude. Cydippe entreated the goddess to reward their affection with the gift that was best for mortals. The goddess heard her prayer; and during the night they both died as they slept in the temple. The Argives raised statues to their memory at Delphi. (Herodot. i. 31.)

CLEOBULUS, one of the Seven Sages, was son of Evagoras, and a native of Rhodes. He seems to have possessed considerable authority in his native city of Lindus, although the precise nature of his office is doubtful. There is still extant in Diogenes Laertius a letter from Cleobulus to Solon; and several sayings are ascribed to him which, if genuine, show him to have been considerably in advance of his age. His daughter Cleobuline was also highly distinguished for her intellectual acquirements and moral worth. She was the author of some of the most famous riddles of antiquity.

CLEOBURY MORTIMER, a market-town in the county of Salop, on the Rea, 26 miles S.E. of Shrewsbury, and 137 from London. Pop. (1851) 1738. It is so called from the Mortimer family, to whom it once belonged, and who had a castle here which was destroyed in the time of Henry II. The church is a fine old building in the early English style. The Clee hills in the vicinity are rich in coal, iron, and limestone. Market-day Wednesday.

CLEOMBROTUS, son of Anaxandrides king of Sparta, who became regent after the battle of Thermopylæ. On the approach of the Persians he was deterred from building a wall across the isthmus of Corinth, by an eclipse of the sun. He died in the 75th Olympiad, and was succeeded by Pleistarchus, the infant son of Leonidas.

CLEOMBROTUS I., son of Pausanias king of Sparta, and brother to Agesipolis I., whom he succeeded on the throne. He was entrusted with the conduct of three successive expeditions against the Bœotians; and to avoid the suspicion of treachery which his former hesitancy and ill-success had inspired at home, he rashly gave battle to Epaminondas at Leuctra on disadvantageous ground, and fell in the engagement, B.C. 371. He was succeeded by his son Agesipolis II.

CLEOMBROTUS II., king of Sparta during the exile of his father-in-law Leonidas II. On the recal of Leonidas (240 B.C.) he was in turn deposed and banished to Tegea, whither he was accompanied by Cheilonis his wife.

CLEOMEDES, a Greek astronomer, whose treatise on the circular theory of the heavenly bodies is still extant. The latest edition is that of Schmidt, Lips. 1832. Cleomedes probably lived in the second and third centuries.

CLEOMENES, a sculptor, son of Apollodorus of Athens, is supposed to be the author of the celebrated statue known as the Venus de' Medici, which bears on its pedestal an inscription to that effect, the genuineness of which has been much disputed, though apparently without good reason. He flourished some time between B.C. 363 and 146. (See Smith's *Dict. of Greek and Rom. Biog. and Mythol.*)

CLEOMENES, king of Sparta, son and successor of Anaxandrides. Before his succession to the throne his sanity was regarded with general suspicion, and he was nearly set aside in favour of his younger brother. His first exploits consisted in the expulsion of the Peisistratidæ from Athens, and in the active support which he gave to the party of Isagoras in opposition to the claims of Cleisthenes. During his absence from Sparta on an expedition against the Æginetans, the intrigues of Demaratus procured his recal; but Cleomenes easily rid himself of the obnoxious colleague, by bribing the priestess at Delphi to pronounce a sentence of illegitimacy against him. About this time he undertook a war against the Argives, whom he defeated in the neighbourhood of Tiryns; and his impiety in burning some of the fugitives within the precincts of the sacred grove of Argus became associated in the popular superstition with his subsequent madness. When the means by which he had procured the abdication of Demaratus became known at Sparta, he fled to Thessaly, and afterwards to Arcadia, where he plotted an invasion of his native country. The dread of his revenge reconciled the Spartans to his recal; but his conduct was so furious that they soon found it necessary to order his confinement in the stocks. This ignominious treatment, however, he did not long survive; for borrowing a knife from the helot who guarded him, he wounded himself so severely that he died.

CLEOMENES II. was the son of Cleombrotus I. and succeeded his brother Agesipolis II., B.C. 370. He reigned 60 years, and had two sons, Acrotatus and Cleonymus. He was succeeded by Areus I. son of Acrotatus.

CLEOMENES III. succeeded his father Leonidas II. (B.C. 236). He was a man of an enterprising spirit, and devoted his energies to effect the restoration of the ancient discipline of Lycurgus. He suppressed the senate because they opposed his designs, poisoned his colleague Eurydamidas, and illegally raised his own brother Eucleidas to the throne. He made war against the Achæans in order to destroy the Achæan league, and for this purpose concluded an alliance with Ptolemy, king of Egypt. Aratus, the general of the Achæans, however, called Antigonus to his assistance; and Cleomenes, defeated at Sellasia, retired into Egypt to the court of Ptolemy Euergetes, whither his wife and children had preceded him as hostages. Ptolemy received him with great cordiality; but his successor, Ptolemy Philopater, jealous of the safety of his crown, treated him with marked disrespect, and threw him into prison on the charge of conspiring against his life. Cleomenes, however, effected his escape; but after a vain attempt to raise an insurrection, he put himself to death (B.C. 220), and his body was exposed on a cross by order of the king.

CLEON, the Athenian demagogue, was the son of Cleænetus, and by trade a tanner. Towards the close of the administration of Pericles, he became distinguished for the virulence of his invectives against the rich; and during the Peloponnesian war his influence over the people determined in a great measure the fate of Attica. (See ATTICA). He fell in a battle when misconducting an expedition into Thrace, B.C. 422. His political career is satirized in several of the comedies of Aristophanes.

CLEON is also the name of a poet of Clusium, who wrote on the Argonautic expedition; of a rhetorician of Halicarnassus, who composed an oration for Lysander; of a Syracusan geographer; of a Magnesian philosopher, who wrote commentaries treating of portentous events; and of a sculptor of Sicyon, whose statues are mentioned by Pausanias.

CLEOPATRA (B.C. 69–30), the celebrated Egyptian queen, was daughter of Ptolemy Auletes, at whose death she ascended the throne along with Ptolemy her younger

brother. A quarrel, however, soon arose between them; and Cleopatra, by the advice of the king's councillors, was expelled the kingdom, and forced to take refuge in Syria. Here she had equipped an army, and was preparing to march into Egypt, when the arrival of Cæsar in pursuit of Pompey opened up an easier path for her ambition. Having gained access to the chamber of the conqueror, her charms and caresses easily procured a decision in her favour; and accordingly she was reinstated in her former power. The death of Ptolemy, and the total defeat of his army, placed her in sole possession of the throne; but Cæsar, dreading the indignation of the Egyptians, with whom she was exceedingly unpopular, divided the kingdom between her and a younger brother, to whom she was nominally married. After the departure of Cæsar from Egypt, Cleopatra followed him to Rome, and was provided with apartments in the palace, where she lived openly as his mistress. After the assassination of Cæsar (B.C. 44) she returned to Egypt, and actively assisted the triumvirate against his murderers. Before the arrival of Antony in Asia Minor, she had poisoned her brother Ptolemy and made herself the sole occupant of the throne. Her voyage up the Cydnus to meet the Roman general is elaborately described by Plutarch, and has been dramatized by Shakspeare. The first use which she made of her power was to procure the death of her sister Arsinoë, and avenge herself on her obnoxious generals. She returned to Egypt attended by Antony, who from this time forward became her slave; and though separated for a while during his visit to Italy, she met him again in Syria on his return from the Parthian expedition, and was publicly acknowledged as his wife. The voluptuous indolence to which Antony now surrendered himself under the fascinations of the queen inspired Augustus with the hope of crushing his rival at a single blow. Partly to disguise his hostile intentions, he proclaimed war against "that accursed Egyptian who had bewitched him." Disappointed of a retreat into Egypt, Cleopatra accompanied the fleet of Antony, and at the battle of Actium (B.C. 31) was the first to give the signal for flight. She entered Alexandria with all the pomp of a triumph, but the desperate situation of her affairs deterred the neighbouring princes to whom she applied for succours from lending her any effectual aid. Finding escape impossible, she resolved to attempt a negotiation with Augustus; and in the hope of winning his favour, did not scruple to sacrifice her paramour for that object. Under pretext of wishing him to die with her, she decoyed Antony to an unfinished mausoleum, in which she had collected her treasures; and there (according to Dion Cassius) Anthony threw himself on his sword and expired in her arms. Her interview with Augustus, however, convinced her that she had nothing to hope from his weakness, and every ignominy to fear from his ambition. At first, to beguile the vigilance of her keepers, who had removed all instruments of death from her apartments, she pretended willingness to go to Rome, and was preparing presents for the Roman empress, when seizing a favourable opportunity she unexpectedly put an end to her life (B.C. 30), either by means of a poisoned comb, or by the poison of an asp. With her ended the dynasty of the Ptolemies, who had filled the throne of Egypt for 300 years. Her son Cæsarion, whom she had borne to Julius Cæsar, was put to death by Augustus; but Alexander, Ptolemy, and Cleopatra, the children of Antony, were reserved to grace his triumph at Rome. The leading features in Cleopatra's character were unbounded ambition and voluptuousness; and to gratify these passions her extraordinary talents, accomplishments, and beauty, were unceasingly employed. She left the library of Pergamus as a monument of her literary tastes; the pages of Plutarch are filled with the record of the refinement which gave a kind of dignity to her excesses; while her haughty and resolute contempt of death filled even the Roman poet with awe. (Hor., *Car.* i. 37.)

CLEOSTRATUS, an astronomer of Tenedos, who, according to Pliny, introduced the division of the zodiac into signs, beginning with Aries and Sagittarius. He flourished about 400 years B.C.

CLEPSYDRA, a water-clock or kind of time-piece used by the Greeks and Romans, which measured time by the discharge of a certain quantity of water in a given time. For the history and construction of clepsydræ, see HYDRODYNAMICS.

CLERC, DANIEL LE (1652-1728), an eminent French physician of great learning, was born at Geneva. He is best known by his very valuable *Histoire de la Médecine*, in three parts, in which he has traced the healing art from its earliest dawn to the time of Galen and the end of the second century. He did not live to finish, as he intended, the more modern history of medicine.

CLERC, *Jean le* (1657–1736), an eminent scholar and biblical critic, was born at Geneva, where his uncle was professor of Hebrew. He became early distinguished for his attainments in classical literature; and after studying under Mestrezat and Turretine, he was ordained at Geneva in 1679. His opinions, however, were more in accordance with the views of Curcellæus and Episcopius—a circumstance which led him to retire from Geneva to Grenoble, and afterwards to Paris. After a short visit to England he removed to Amsterdam, where in 1684 he became professor of philosophy, belles-lettres, and Hebrew, in the Remonstrant College. In 1728, while lecturing, he lost the use of his speech through a paralytic stroke; and his memory failing, he lingered on till his death in a state bordering on idiocy. As a critic, Le Clerc may be ranked the first of his time; but the Socinianizing tendency of his views estranged him from the great mass of Protestant divines. His polemical works in general betray a somewhat bitter and dogmatic tone, while his miscellaneous writings bear the marks of hasty composition.

His works are exceedingly voluminous. The best known are his Latin commentaries on several books of the Bible; his *Ars Critica; Harmonia Evangelica;* Translation of the New Testament into French; *Traité de L'Incrédulité;* and the *Parrhasiana, ou Pensées diverses sur les Matières de Critique, d'Histoire, de Morale, et de Politique.* Besides these he edited the *Bibliothéque Historique et Universelle*, 26 vols.; the *Bibliothéque Choisie*, 28 vols.; and the *Bibliothéque Ancienne et Moderne*, 29 vols. He also published several editions of the ancient classics.

CLERC, *Sebastian le* (1637–1714), an eminent French engraver, was born at Metz. After having held the office of engineer to the Marshal de la Ferté, he went to Paris in 1665, and applied himself to designing and engraving with such success, that M. Colbert gave him a pension of 600 crowns. In 1672 he was admitted into the royal academy of painting and sculpture; and in 1680 was made professor of geometry and perspective in the same academy. Besides a vast number of designs and prints, he published *A Treatise on Theoretical and Practical Geometry, A Treatise on Architecture*, and other works. Le Clerc was an excellent artist, and his smaller works, in which he was most successful, are only equalled by the engravings of Callot and Della Bella. His most esteemed prints are, 1. The *Passion of our Saviour*, on 36 small plates; 2. The *Miracle of Feeding the Five Thousand;* 3. The *Elevation of the large Stones used in Building the Front of the Louvre;* 4. The *Academy of the Sciences*, a middle-sized plate, lengthwise; 5. The *May of the Gobelins*, a middle-sized plate, lengthwise; 6. The *Four Conquests*, large plates, lengthwise, representing the taking of Tournay, the taking of Douay, the defeat of the Comte de Marsin, and the Switzerland Alliance; 7. The *Battles of Alexander*, from Le Brun, six small long plates, including the title, which represents the picture gallery at the Gobelins; and, 8. The *Entry of Alexander into Babylon*, a middle-sized plate, lengthwise, in the first impressions of which the

face of Alexander is seen in profile, but in the second it is a three quarter face, and therefore called *the print with the head turned.*

CLERGY, Benefit of, an obsolete, but once very important feature in the English criminal law. It was a relic of the claim of exemption from the authority of the common law tribunals, on the part of the clergy, and marked the extent to which the demand was acceded to in England. The conclusion of the protracted conflict was, that the common law courts abandoned the extreme punishment of death assigned to some offences, when the person convicted was a *clericus*, in holy orders, and the church was obliged to accept the compromise and let a secondary punishment be inflicted. For the more atrocious crimes the partial exemption was not obtained; and hence offences came to be divided into clergyable and unclergyable. According to the common practice in England of working out modern improvements through antiquated forms, this exemption was made the means of modifying the severity of the criminal law. It became the practice for every convict to claim and be allowed the benefit of clergy; and when it was the intention by statute to make a crime really punishable with death, it was awarded "without benefit of clergy." A full account of the origin and progress of the system will be found in the 28th chapter of the fourth book of Blackstone's commentary. The benefit of clergy in cases of felony was abolished in the modifications of the criminal law by Sir Robert Peel in 1827 (8th Geo. IV. cap. 28.) (J. H. B.)

CLERK, a term applied to ministers of religion, and to some civil officers. The post-classical *clerus* and *clericus* have been satisfactorily traced to the Greek κλῆρος, a portion or heritage. In the distribution of the portions of the tribes under the Jewish dispensation, it was called the heritage of the tribe of Levi to receive the contributions of the faithful as persons set apart for the worship of God, and not endowed with a fixed inheritance. Hence the word came to be applied to the ministers or clergymen of the early church, and its meaning obtained an extended application to all men of learning, and persons who could compose or write documents, since these qualifications were almost the exclusive possession of the clergy. In the French dictionaries of Moreri and the Trevoux, an account of a variety of offices, lay and ecclesiastical, will be found under the head *Clerc*. In Britain, during the subsistence of monastic establishments, the term generally implied a secular priest in contradistinction to a regular.

Among the older English writers, the word clerk was almost invariably applied to a clergyman; and this is still its legal meaning when employed in formal documents, without any explanatory phraseology. In common language, it came to be synonymous with scribe, and has been applied to a large class of officers of varied functions and positions, from men who partake of the character of ministers of state down to humble copyists, whose qualification consists in the ability to write a legible hand. The rights and duties of clerks, involving the responsibilities which they may bring on their employers, are an important practical part of the law, but it comes properly under that general branch applicable to employer and employed, which it is usual to discuss under the head master and servant.

The proceedings of the two houses of parliament, of the various courts of justice, and of the several ministerial departments, are generally drawn and recorded by clerks who hold a position corresponding with the importance of their functions. The clerk of the parliaments is at the head of the ministerial officers, at the disposal of the legislature. He is considered as specially attached to the House of Lords in the separate proceedings of the two houses. The House of Commons is attended by a clerk of the House of Commons, who is an equally high and important officer, though nominally he is the deputy of the clerk of the parliaments. They are aided by a staff of assistants, and other subordinate clerks. Though the functions of these officers in attending to the order of business, authenticating bills and other documents, and drawing out the routine proceedings, are very onerous and distinguished, it is an important constitutional fact that the English legislature was ever jealous of allowing stipendiary officers to draw and put in terms their legislative acts. While in other countries the clerk or recording officer made up from his own account of what had taken place the legislative act in which it was embodied, the English parliament had the terms of the measure laid before it *verbatim* in the shape of a bill, leaving nothing to the discretion of a permanent stipendiary officer. Hence this class of functionaries failed to obtain in England the influence they have held elsewhere. In Scotland, the clerk of the parliaments and of the supreme courts of justice was a high officer of state, called the Lord Clerk Register, and the character of his influence may be inferred by a statement in Sir George M'Kenzie's annals, that the Clerk Register under Charles II. claimed some reward for drawing the acts of parliament favourably to the prerogative.

Until a comparatively late period, there were a large number of clerkships, connected chiefly with the courts of justice, having ancient and quaint names derived from some incident of their origin. Thus, there was the Clerk of the Hanaper and the Clerk of the Petty-bag, said to be so distinguished from the kind of receptacle—a hamper in the one case, and a little bag in the other—in which the writs in their custody were deposited. The Clerk of the Pells wrote on pells, or skins, while the Clerk of the Pipe, the head of an important department in the exchequer, was so named from the pipe-shaped roll in which he extended his accounts of debts to the crown. The reason why these venerable distinctions were religiously preserved was because they had each gradually accumulated an incrustation of fees and privileges, which made them valuable objects of patronage. The "six clerks" of the court of chancery, besides their emoluments, had the privilege of each naming ten of the "sixty clerks," who were agents licensed to conduct a particular kind of business; and in a similar manner a body of clerks in the privy-council office of Scotland, called Clerks to the Signet, acquired the peculiar privileges enjoyed by the respectable body of practitioners still called clerks, or more commonly Writers, to the Signet. The early jobbing in the patronage of the six clerks became picturesquely conspicuous in the pages of Clarendon. Sir Julius Cæsar, a very aged man, being master of the rolls, proposed to provide for his son by making him one of the six clerks. The patronage was considered a perquisite of the master of the rolls; but on this occasion the treasurer Portland gave it to another person, who paid L.6000 for it. It was represented to the treasurer that he owed Sir Julius some indemnity; and desiring a memorandum of the matter, a slip of paper was given to him with the words "Remember Cæsar" written on it. The careless lord treasurer allowed this memorandum to lie unnoticed until, after its cause was forgotten, it was discovered at a period of political alarm. He consulted his friends about the mystical document, and, as Clarendon says, "After a serious and melancholy deliberation, it was agreed that it was the advertisement from some friend who durst not own the discovery; that it could signify nothing but that there was a conspiracy against his life, and they all knew Cæsar's fate by contemning or neglecting such animadversions."

Several public investigations, and especially those of the finance committees of 1797 and 1808, showed that the clerkships connected with the courts of justice went to increase the proper official income of statesmen, or to provide pensions for their relations. Thus in 1808 it

appeared that the office of clerk of the crown in the king's bench, with an income of L.12,511, was partitioned between the two sons of an influential marquis; the clerkship of the pells in Ireland was held by an eminent statesman with a salary of L.3500; and the clerkship of the common pleas there, with an income of L.11,094, belonged to an earl. The report of 1797 showed that the clerk of the hanaper in chancery was an earl and his heirs; and the report of 1808 showed the office in the possession of two ladies, his "sisters and co-heiresses." In some instances the clerkships appeared to be held in trust for persons who must have been supposed too young or too imbecile to grant the necessary receipts for the salary. What facilitated the existence of such offices, but at the same time rendered them the more oppressive, was that the incomes were derived from old fees on litigants, frequently commenced without warrant, and gradually acquiring an authoritative existence through long inveterate custom. At the time when such large incomes were thus drawn, the working clerks were often remunerated with a parsimony inimical to the public service. The tendency of late legislation has been to adjust the official staff of each department to its existing operative exigencies. Hence the clerkships with quaint names have gradually been abolished. Of the varied class of such offices which had to be mentioned as existing institutions in the previous editions of this work, some notion may be formed from what follows.

By two statutes of the year 1832, for regulating the establishments of the common law side of the exchequer and the court of chancery, several old consuetudinary clerkships were abolished, and among them that of the clerk of the pleas in the former, and in the latter the offices of clerk of the hanaper, clerk of the crown in chancery, clerk of the patents, clerk of custodiers of lunatics and idiots, clerk of the presentations, clerk of enrolments in bankruptcy, and clerk of dispensatories and faculties (2d and 3d Will. IV. cap. 10, 111). A list of offices of this kind, abolished, occupies a considerable schedule in an act passed in 1837 "to abolish certain offices in the supreme courts of common law, and to make provision for a more effective and uniform establishment of officers in those courts" (7th Will. IV. and 1st Vict. cap. 30). Among the offices so abolished were, on the plea side of the queen's bench, the chief clerk, the clerk of the rules, the clerk of the papers, the clerk of the dockets and judgments, the clerk of the declarations, the clerk of the common bails or appearances estreats and posteas, the clerk of the inner and upper treasurers, clerk of the outer treasury, clerks of nisi prius, clerk of the errors, clerk of the outlawries and filacer and exigenter; in the court of common pleas, the several clerks, of the judgments, of the outlawries, of the reversals of outlawries, of the dockets, of the warrants, enrolments, and estreats, of the essoigns, of the treasury, of the juries, of the errors, of the jurata, and of the supersedeas; in the exchequer court, there were abolished the clerk of the rules, the clerk of the errors, and the clerk of the pleas. (J. H. B.)

CLERKE, Captain Charles, a celebrated English navigator, spent his youth in the navy, and was present at several actions during the war of 1755. In the engagement between the Bellona and Courageux he was carried overboard along with the mizen-top mast of the Bellona, but was picked up without having received any injury. He made his first voyage round the world as midshipman under Commodore Byron, and was afterwards on the American station. In 1768 he sailed round the world a second time in the Endeavour, on board of which he was raised to a lieutenancy. He returned in 1775, and was soon afterwards appointed master and commander. Under Captain Cook he was appointed captain of the Discovery; and on the death of that officer he succeeded to the chief command. His health, which had long been feeble, began rapidly to fail from the cold to which he was exposed while searching for a passage between Asia and America; and he died Aug. 22, 1778, when within view of the coast of Kamtschatka.

Clerk, *John, of Eldin* (1730–1812), the author of the celebrated naval manœuvre of *Breaking the Line*, which led to Lord Rodney's victory over the French under De Grasse. (See War § Naval Tactics). It is worthy of observation, as a singular fact, that a man who has written so distinctly on the mode of managing a fleet should never have made a single voyage. Sir Howard Douglas has claimed the invention of this manœuvre for Lord Rodney, but on very slender grounds.

CLERMONT, or Clermont Ferrand, the ancient *Augustonemetum*, a city of France, capital of Basse Auvergne and of the department of Puy-de-Dôme, situated on a hill composed chiefly of volcanic tufa, in the fertile district of Limagne, and surrounded on the S. and W. by a line of mountains, of which the Puy-de-Dôme is the culminating point. The city lies in Lat. 45. 46. N., Long. 3. 5. E., and is 220 miles S. by E. from Paris. Pop. (1851) 30,563. It is composed of the two towns of Clermont and Mount Ferrand, connected by a fine avenue of walnut trees and willows, two miles in length. The streets are generally ill laid out, narrow, and crooked; and the houses are built of dull gray lava, which has a gloomy effect. It has several handsome squares ornamented with fountains, and is well supplied with water brought by subterranean conduits from Royat, a league distant. The principal public building is the cathedral—a Gothic edifice of the thirteenth century, and though still unfinished its interior is considered one of the finest existing specimens of Gothic architecture. The church of Nôtre-Dame-du-Port is curiously decorated externally with mosaic work, bas-reliefs, &c., and is very ancient—parts of it dating from 870. Clermont has also a university, academy, royal college, botanic garden, public library of 18,000 vols., museums of natural history and antiquities, two hospitals, theatre, &c. The manufactures are woollen and linen goods, silk stockings, paper, cutlery, jewellery, &c. Being the entrepôt for the produce of the surrounding departments, it carries on a considerable trade in hemp, flax, corn, wine, cheese, wool, hides, and cattle. In the suburb of St Alyre to the N.W. of the city is a remarkable calcareous spring, the copious deposits of which have formed a curious natural bridge. At Clermont was held the celebrated council of 1095, which gave rise to the first crusade. Pascal was a native of Clermont.

Clermont de Lodeve, a city of the department of the Herault, in France, on the river Ergue. It contains 791 houses and 6199 inhabitants.

Clermont *Manuscript*, a stichometric copy of St Paul's Epistles (including "Hebrews"), found in the monastery of Clermont in France, and first used by Beza, together with the Cambridge MS., in preparing his New Testament. This copy is in octavo, and written on fine vellum in Greek and Latin. It is complete with the exception of a few verses. The Latin text gives the oldest form of the Latin translation made as early as the second century, but the handwriting is that of the second half of the sixth century. The MS. itself was in the possession of Morinus, and is now deposited in the imperial library at Paris (No. 107). It was edited, with a facsimile, by Tischendorf in 1852.

CLEROMANCY (κλῆρος, lot, μαντεία, divination), a divination by throwing dice, and observing the points or marks turned up.

CLEVELAND, a city, capital of the county of Cuyahoga, state of Ohio, North America, occupies a commanding situation on lake Erie, at the mouth of the Cuyahoga river, and at the northern termination of the Ohio canal. The town is built principally upon a gravelly plain 80 feet above the lake; the streets are wide, crossing each other at right angles, and are ornamented with many elegant buildings. Near the centre is a large public square of ten acres, divided into

four equal parts by intersecting streets, and neatly inclosed and shaded by trees. The harbour, one of the best on the lake, is formed by the mouth of the Cuyahoga, with a pier on each side, 200 feet apart, and extending 425 yards into the lake. In 1850 the coastwise imports amounted in value to $7,030,957; exports $6,855,556. The principal part of its trade, however, is carried on by the canals and railroads, which connect it with Portsmouth, Pittsburg, Cincinnati, and other towns. In 1799 there was only one family residing here; and in 1825 only about 500 persons; while in 1850 the population amounted to 17,034. In 1814 it was incorporated as a village, and in 1836 as a city.

Cleveland, *John* (1613–59), an English poet of some eminence in his time, who, during the civil war, engaged as a literary champion in the royal cause against the parliamentarians. His works, which consist of poems, characters, orations, epistles, &c., were printed in 8vo in 1677. The last edition appeared so long ago as 1687; yet Cleveland was in his day esteemed one of the best of the English poets, and enjoyed a popularity far surpassing that of Milton.

CLEVES, Cleve, or Kleve, a walled town of Rhenish Prussia, government of Dusseldorf, capital of a circle, and formerly of the duchy of the same name, 46 miles N.W. of Dusseldorf. It is a neatly-built town in the Dutch style, situated on a declivity in a fertile district near the Dutch frontier, and about two miles from the Rhine, with which it is connected by a canal. The old castle (formerly the residence of the dukes of Clèves, and in which Anne of Clèves, one of the wives of Henry VIII., was born) has a massive tower 180 feet high, built in 1439, and commanding a very extensive view. Clèves has two Roman Catholic and three Protestant churches, a synagogue, high school, and house of correction. Its chief manufactures are linens, cottons, silks, woollens, flannels, tobacco, &c. In the vicinity are a royal park and a zoological garden. Pop. (1849) of town 8401; of circle 49,335. The district of Clèves, situated on both sides of the Rhine, was governed by counts from the ninth century, till in 1417 it was raised to a duchy by the Emperor Sigismond. On the death of Duke William in 1609 without issue, the duchy fell to Sigismond, elector of Brandenburg, who had married a niece of the late duke. In 1805 it was ceded by Prussia to France; and in 1806 was made a grand duchy by Napoleon, and bestowed upon Murat. In 1815 it was restored to Prussia.

CLEW, in nautical language, the lower corner of a square sail, and the after corner of a fore-and-aft sail. Clew-garnet is a tackle for hauling up the clew of a foresail or a mainsail.

CLIENT (Lat. *cliens*), among the Romans, a citizen that put himself under the protection of a man of distinction and influence, who, in respect of that relation, was called *patronus*. The patron afforded his protection, advice, and even pecuniary assistance to his client on certain occasions; and the client gave his vote for his patron, when the latter sought any office for himself or his friends. Clients owed respect to their patrons, and patrons owed their clients protection. This connection was hereditary, descending from one generation to another. The client bore the name of his patron, and attended him in war as his vassal Hence illustrious families were proud of the number of their clients, and strove to increase the number of those transmitted to them by their ancestors. The connection too between a master and his liberated slave was expressed by the same terms.

The right of patronage, it is said, was instituted by Romulus, in order to unite the rich and the poor in such a manner as that the one might live without contempt, and the other without envy; but the condition of a client became in course of time little else than a species of servitude. Dionysius has given a summary of the mutual rights and obligations between patron and client.

Client is now used to signify a party in a lawsuit who entrusts his cause to a counsellor or a solicitor.

CLIFDEN, a seaport-town of Ireland, county of Galway, at the head of an inlet of Ardbear harbour, 46 miles N.W. of Galway, and 178 from Dublin. It has a Gothic parish church, Roman Catholic chapel, market-house, bridewell, workhouse, hospital, and dispensary. Vessels of 200 tons can come up to the town. Exports, grain, herrings, butter, &c. Pop. (1851) 2252, including 639 in workhouse.

CLIFTON, a suburb of Bristol, and generally considered as forming part of the city, is picturesquely situated on the sides and summit of a precipitous limestone-hill overhanging the Avon. Pop. (1851) 17,634. It is a favourite residence of the wealthier inhabitants of Bristol, and is celebrated for its hot well spring. See Bristol.

CLIMACTERIC (from *climacter*, a ladder, gradation), among physicians, a critical year in a person's life. According to some, this is every seventh year; but others admit only the years produced by multiplying 7 by the odd numbers 3, 5, 7, and 9, to be climacterical. These years have been supposed from remote antiquity to bring with them some remarkable vicissitudes with respect to health and fortune. The grand climacteric is the 63d year; but some, making two, add to this the 81st. The other remarkable climacterics are the 7th, 21st, 35th, and 49th.

CLIMATE.

Ancient use of the word *climate*.

The word *Climate*, or κλίμα, being derived from the verb κλίνειν, *to incline*, was applied by the ancients to signify that obliquity of the sphere with respect to the horizon from which results the inequality of day and night. The great astronomer and geographer Ptolemy distinguished the surface of our globe, from the equator to the arctic circle, into climates or parallel zones, corresponding to the successive increase of a quarter of an hour in the length of midsummer-day. Within the tropics, these zones are nearly of equal breadth; but, in the higher latitudes, they contract so much, that it was deemed enough to reckon them by their doubles, answering consequently to intervals of half an hour in the extension of the longest day. To compute them is an easy problem in spherical trigonometry. As the sine of the excess of the semidiurnal arc above a quadrant is to the radius, so is the tangent of the obliquity of the ecliptic, or of 23° 28′, to the cotangent of the latitude. The semidiurnal arcs are assumed to be 91° 52½′, 93° 45′, 95° 37½′, 97° 30′, &c.; and the following table, extracted from Ptolemy's great work, will give some general idea of the distribution of seasons over the surface of our globe:—

Climate or Parallel.	Latitude.	Length of Midsummer Day.	Breadth of Zone.	Climate or Parallel.	Latitude.	Length of Midsummer Day.	Breadth of Zone
I.	0° 0′	12h.00	4° 15′	XIV.	43° 4′	15″ 15	1° 57′
II.	4 15	12 15	4 10	XV.	45 1	15 30	1 50
III.	8 25	12 30	4 5	XVI.	46 51	15 45	1 41
IV.	12 30	12 45	3 57	XVII.	48 32	16 00	1 32
V.	16 27	13 00	3 47	XVIII.	50 4	16 15	1 36
VI.	20 15	13 15	3 38	XIX.	51 40	16 30	1 10
VII.	23 51	13 30	3 21	XX.	52 50	16 45	1 40
VIII.	27 12	13 45	3 10	XXI.	54 30	17 00	1 30
IX.	30 22	14 00	2 56	XXII.	55 00	17 15	1 00
X.	33 18	14 15	2 42	XXIII.	56 00	17 30	1 00
XI.	36 00	14 30	2 35	XXIV.	57 00	17 45	30
XII	38 35	14 45	2 21	XXV.	58 00	18 00	
XIII.	40 56	15 00	2 9	XXVI.	59 30	18 30	

These numbers are calculated on the supposition that the obliquity of the ecliptic was 23° 51′ 20″, to which, accord-

ing to the theory of Laplace, it must have actually approached in the time of Ptolemy. They seem to be affected by some small errors, especially in the parallels beyond the seventeenth, as the irregular breadth of the zone abundantly shows; but they are, on the whole, more accurate than those given by Varenius.

Ptolemy describes the general appearances which the heavens will present on each parallel, and assigns the corresponding lengths of the shadow of the gnomon at both solstices. He justly maintains, in opposition to the more ancient opinion, that the equatorial region is habitable, since the action of the sun, not continuing long vertical, is there mitigated; but he will not venture to describe the inhabitants, because no person, he says, having yet penetrated so far south, the reports circulated respecting them appeared to be merely conjectural. He therefore passes over the first parallel to the second.

This *second* parallel, then, according to Ptolemy, runs through the isle of Taprobana, supposed to be Ceylon, in the latitude of 4° 15′. The *third* parallel, in the latitude of 8° 25, traverses the gulf of *Adulitus*. The *fourth* parallel crosses the *Adulitic* gulf, in latitude 12° 45′. The *fifth* parallel passes through the isle of *Meroe*, in Upper Egypt, at latitude 16° 27′. The *sixth* parallel runs through the territory of the *Napati*, in latitude 20° 15′. All these climates or parallels lying below the tropic, the inhabitants are therefore *Amphiscians*, or see the sun pass twice over their heads in the course of the year. The *seventh* parallel, at the latitude of 23° 51′, and consequently bordering the tropic, runs through Syene, in Upper Egypt. The *eighth* parallel, in latitude 27° 12′, traverses Ptolemais, in the Thebaid. The *ninth* zone, corresponding to a day of fourteen hours of length, passes through Lower Egypt, at the latitude of 36° 12′. The *tenth* parallel, in latitude 33° 18′, runs through the middle of Phœnicia. The *eleventh* parallel, at the thirty-sixth degree of latitude, passes through the isle of Rhodes. The *twelfth* parallel, in latitude 38° 35′, crosses Smyrna. The *thirteenth* parallel traverses the Hellespont, in latitude 40° 56′. The *fourteenth* parallel, in latitude 43° 4′, runs through Marseilles. The *fifteenth* parallel passes through the middle of the Pontic Sea, in latitude 45° 1′. The *sixteenth* parallel runs through the sources of the Ister or Danube, in latitude 46° 51′. The *seventeenth* parallel, corresponding to a day of sixteen hours in length, traverses the mouths of the Borysthenes, in latitude 48° 32′. The *eighteenth* parallel, at the latitude of 50° 4′, crosses the Palus Mæotis. The *nineteenth* parallel passes through the most southern part of Britain, in latitude 51° 40′. The *twentieth* parallel crosses the mouths of the Rhine, in latitude 52° 50′. The *twenty-first* parallel passes through the mouths of the Tanais, in latitude 54° 30′. The *twenty-second* parallel, at the fifty-fifth degree of latitude, traverses the country of the *Brigantes*, in Great Britain, that is, the southern and larger portion of this island, reckoning from the Frith of Forth. The *twenty-third* parallel, in the fifty-sixth degree of latitude, passes through the middle of Great Britain. The *twenty-fourth* parallel, at the latitude of 57°, runs through *Caturactonium*, in Great Britain. The *twenty-fifth* parallel, corresponding to a day of eighteen hours, runs through the southern parts of Little Britain, in latitude 58°. The *twenty-sixth* parallel, corresponding to a day of 18½ hours in length, traverses the middle of Little Britain, in latitude 58° 30′. It should be observed that the latitudes of the places in our own island are most inaccurately given by Ptolemy, and generally advanced about two or three degrees farther north than their true position. By Little Britain he meant undoubtedly that part of Scotland which lies on the north side of the Friths of Forth and Clyde, and forms almost a peninsula.

The high zones become so narrow, that Ptolemy separates the *twenty-sixth* to an interval of half instead of a quarter of an hour in the length of the day; but he thinks it superfluous to extend this subdivision farther into such remote and inhospitable countries. Resuming the calculation, however, he places the parallel where midsummer day is prolonged to nineteen hours, in the latitude of 61°, or the north of Little Britain. The parallel of 19½ hours would pass through the Ebudes, Hebrides, or Western Isles, in latitude 62°. The parallel of twenty hours runs through the island of Thule, in the latitude of 63°. The parallel of twenty-one hours would traverse the unknown Scythian nations, in latitude 64½°. The parallels of twenty-two and twenty-three hours would run through the latitudes of 65½° and 66°. He places in latitude 66° 8′ 40″ the arctic circle itself, where the sun does not set during the whole of midsummer day. Within this circle the inhabitants are *Periscians*, or have the sun lingering above the horizon during part of the summer, and the shadow of the gnomon successively projected in every direction. In the latitude of 67°, the sun continues almost a whole month above the horizon; in the latitude of 69½°, he shines two months; in the latitudes 73⅓°, 78⅓°, and 84°, that luminary displays his presence for three, four, and five months. At the pole itself, the sun appears, during the space of six months, describing circles parallel to the horizon.

Modern application of this word.

Climate, in its modern acceptation, signifies that peculiar condition of the atmosphere in regard to heat and moisture which prevails in any given place. The diversified character which it displays has been generally referred to the combined operation of several different causes, which are chiefly reducible, however, to these two; *distance from the equator*, and *height above the level of the sea*. Latitude and local elevation form, indeed, the great bases of the law of climate; but as we shall soon see, other causes are not to be neglected in the estimation of differences of climate.

If we dig into the ground, we find the temperature to become gradually more steady, till we reach a depth of perhaps forty or fifty feet. When this perforation is made during winter, the ground gets sensibly warmer till the limit is attained; but in summer, on the contrary, it grows always colder, till it has reached the same limit. At a certain depth, therefore, under the surface, the temperature of the ground remains quite permanent.

It would be a hasty conclusion, however, to regard this limit of temperature as the natural and absolute heat of our globe. If we dig on the summit of a mountain, or any very elevated spot, we shall discover the ground to be considerably colder than in the plain below; or, if we make a similar perforation on the same level, but in a more southern latitude, we shall find greater warmth than before. The heat thus obtained at some moderate depth is hence only the mean result of all the various impressions which the surface of the earth receives from the sun and the atmosphere.

The method employed hitherto for ascertaining the temperature at different depths under ground, consists in digging a hole, and burying a sluggish thermometer for several hours, or the space of a whole night. The celebrated naturalist and accurate observer, Saussure, in the month of October 1785, made an interesting set of observations on the banks of the Arve, near Geneva. By digging downwards on successive days, he reached at last the depth of 31 feet. While the surface of the ground had retained a heat of 60°·3 by Fahrenheit's scale, the temperature of the earth at the depth of 4 feet was 60°·8, at 16 feet 56°, at 21 feet 53°·6, and at 28 feet 51°8. A thermometer buried 31 feet deep was found, when taken up in summer, to stand at 49°·5, and when raised in winter, to indicate 52°·2. Notwithstanding this great depth, therefore, it had still felt the vicissitude of the seasons, having varied 2°·7 in the course of the year. The extreme impressions must have taken six months to penetrate to the bulb, since the temperature was lowest in summer and highest in winter.

Temperature below surface of the earth.

But this plan of observing is clumsy and imperfect, there not being sufficient time to allow the mass of earth to regain its proper degree of heat, and too much for the instrument to retain its impression unaltered before it can be raised up and observed. In order to throw distinct light on a subject so curious and important, Robert Ferguson, Esq. of Raith, a gentleman whose elegant mind is imbued with the love of science, caused a series of large mercurial thermometers, with stems of unusual length, to be planted in his spacious garden at Abbotshall, about 50 feet above the level of the sea, and near a mile from the shore of Kirkcaldy, in latitude 56° 10′. The main part of each stem having a very narrow bore, had a piece of wider tube joined above it; and to support the internal pressure of the column of mercury, the bulbs were formed of thick cylinders. The instruments, inclosed for protection in wooden cases, were then sunk beside each other to the depths of one, two, four, and eight feet, in a soft gravelly soil, which turns, at four feet below the surface, into quicksand, or a bed of sand and water. These thermometers were carefully observed from time to time by Mr Charles Norval, the very intelligent gardener at Raith; and we have had access to a register of their variations for nearly three years. It thence appears that, in this climate, and on naked soil, the frost seldom or never penetrates one foot into the ground. The thermometer at that depth fell to 33° of Fahrenheit on the 30th December 1815, and remained at the same point till the 12th February 1816; but in the ensuing year it descended no lower than 34°, at which it continued stationary from the 23d December 1816 to 1st January 1817. At the same depth, of one foot, it reached the maximum 58° on the 13th July 1815, but in the following year it rose only to 54° on the 21st July; and in the year 1817 it mounted to 56° about the 5th July. This thermometer, in the space of three years, travelled, therefore, over an interval of 25°, the medium being $45\frac{1}{2}$, and attained its highest and lowest points about three weeks after the solstice of summer and of winter.

Depth which frost penetrates.

The thermometer planted at the depth of two feet sunk to 36° on the 4th February 1816; but it stood at 38° about the beginning of January 1817. It rose to 56° on the 1st of August 1815; but in the next year it reached only 53° on 24th July; and, in 1817, it again reached 56° on 10th July. At the depth of two feet, the extreme variation was therefore 20°; and the maxima and minima took place about four or five weeks after either solstice.

The thermometer of four feet depth had sunk to 39° about the 11th February 1816, and was stationary at 40° near the 3d February 1817. It rose to 54° on the 2d August 1815, and stood at 52° during the greater part of August and September in the years 1816 and 1819. It ranged, therefore, only 15°, the mean being $46\frac{1}{2}$°, and the extreme points occurring near two months after either solstice.

The thermometer whose bulb was planted eight feet deep descended to 42° on the 16th February 1816, but stood at $42\frac{1}{2}$° on the 11th February 1817. It rose to $51\frac{1}{2}$° on the 11th September 1815, fell to 50° on the 14th September 1816, and mounted again to 51° on the 20th September 1817. This thermometer had, therefore, a range of only $9\frac{1}{2}$°, the medium temperature being $46\frac{3}{4}$°, and the extremes of heat and cold occurring nearly three months after the solstice of summer and of winter.

These observations are quite satisfactory, and exhibit very clearly the slow progress by which the impressions of heat or cold penetrate into the ground. It will not be far from the truth to estimate the rate of this penetration at an inch every day. The thermometers hence attained their maximum at different periods, though in a tolerably regular succession. The mean temperature of the ground, however, seemed rather to increase with the depth; but this anomaly evidently proceeded from the coldness of the two successive summers, and particularly that of 1816, which occasioned such late harvests and scanty crops. Thus the thermometer of one foot indicated the medium heat of only 43°·8 during the whole of the year 1816. But it will be satisfactory to exhibit the leading facts in a tabular form. The following are the mean results for each month, only those for December 1817 are supplied from the corresponding month in 1815.

	1816.				1817.

If the thermometers had been sunk considerably deeper, they would no doubt have indicated a mean temperature of 47°·7. Such is the permanent temperature of a copious spring which flows at a short distance, and about the same elevation, from the side of a basaltic or greenstone rock. Profuse fountains and deep wells, which are fed by percolation through the crevices of the strata, furnish the surest and easiest mensuration of the temperature of the earth's crust. The body of water which bursts from the caverns of Vaucluse, and forms almost immediately a respectable and transclucid river, has been observed not to vary in its temperature by the tenth part of a degree, through all the seasons of the year. It is, therefore, an object highly important for scientific travellers to notice the precise heat of springs in favourable situations, as they issue from their rocky beds. Such observations would generally afford the medium temperature of any climate. It is only requisite to exclude the superficial and the thermal springs, which are not difficult to distinguish.

It must, however, be recollected that at considerably greater depths a higher temperature is found. This was first observed in very deep mines, and was by some ascribed to the heat of the miners' candles and of their bodies, or to the sudden evolution of the latent heat of air extricated by its condensation in such confined spaces. But the temperature has been found to be too high for such causes; and the great increase of heat observed in the waters of Artesian wells, according to their profundity, as was ably pointed out by Arago, is a strong proof of the existence of a source of temperature within the earth itself, independent of solar influence. That this cause, however, does not affect the temperature of the outer crust of our earth is obvious from the steadiness of mean temperature in different places, which Arago has shown, over Europe at least, to have been for some centuries, as nearly as we can judge from the freezing of certain rivers, lakes, and seas in winter, about what it is still found to be. It is, no doubt, the effect of radiation, and of the movements of the atmosphere, and of the ocean which have combined to produce the steadiness of the mean temperature.

Mayer's rule for calculating the mean temperature of any place.

From a comparison of meteorological observations made at distant points on the surface of our globe, the celebrated astronomer Professor Mayer of Göttingen has endeavoured to discover an empirical law which connects the various results. Round the pole, the mean temperature he assumes

to be at the precise limit of freezing, since the fields of ice accumulated in that forlorn region seem at this present period neither to increase nor diminish. But under the equator the medium heat on the level of the sea Bouguer estimated at 84½° of Fahrenheit, or 29 centesimal degrees, the division of the thermometric scale which is the best suited to philosophical purposes. At the middle point, or the latitude of 45° the temperature is found to be about 14½° centigrade. From that centre the heat diminishes rapidly northwards, and increases with equal rapidity towards the south. Hence the mean temperature of any place, at the level of the sea, is calculated in centesimal degrees, by multiplying the square of the cosine of the latitude into the constant number 29; or it is found by multiplying the supplemental versed sine of double the latitude into 14½°. The variation of temperature for each degree of latitude is hence denoted centesimally by half the sine of double the latitude; being in fact this quantity diminished in the ratio of 58, the double of 29, to 57·3, the length of an arch equal to the radius. From these data the following table is computed; in which are likewise annexed the corresponding degrees of Fahrenheit's, with the successive differences.

Lat.	Centesimal.	Dif.	Fahrenheit	Dif.	Lat.	Centesimal.	Dif.	Fahrenheit.	Dif.	Lat.	Centesimal.	Dif.	Fahrenheit	Dif.
0	29°·00	·00	84°·2	·00	30	21°·75	·43	71°·1	·77	60	7°·25	·44	45°·0	·79

This table, and the formula on which it is calculated, though once supposed to afford a pretty accurate idea of the mean temperature of different latitudes at the level of the sea, can now only be received as an ingenious though erroneous speculation: for the researches of later observers have shown that it accords not with observations either in high latitudes, or in regions 70° or 80° W. or E. of the meridians of Paris and London. At the time the astronomer Mayer published his formula, the mean temperature of scarcely three or four points on the globe were accurately ascertained: his formula is therefore founded on very imperfect data, and the subsequent labours of travellers and navigators have demonstrated the fallacious grounds from which it was deduced. We may also remark that Mayer was misled by Bouguer's too high estimate of the equatorial mean temperature, which is assumed to be 24° of Réaumur; but the more accurate determinations of Humboldt make it no more than 22° Réaumur, which is equivalent to 81°·5 Fahrenheit. Among the earliest to afford more correct data we must reckon British navigators and scientific travellers. Humboldt, in discussing the difference of terrestrial temperature, says—"To begin with the extreme north, I shall here mention a man in the first place whom the dangerous occupation of whale fishing has not prevented from carrying on the most refined meteorological observations. Scoresby has for the first time determined the mean temperature of the polar seas, which he has ascertained between the volcanic island of Jan Mayen and that part of East Greenland discovered by himself. Parry, Sabine, and Franklin have for several years been employed in investigating the temperature of the atmosphere and the sea in the polar regions; they have penetrated to Port Bowen and Melville Island, therefore nearly to 75° N. Lat., and they have in this arduous task displayed a perseverance of which we scarcely find a parallel in the history of human exertions and struggles against the elements."

Humboldt also pays a high compliment to the exertions of Captain Weddell, who has overthrown a prejudice that was even sanctioned by the illustrious Cook, viz., that the south polar ice renders the antarctic far less accessible than the arctic seas. Since Humboldt's memoir was written, the discoveries of Sir James Ross far in the antarctic regions have confirmed that observation. The information afforded by the arctic voyages are so important and well established, that we hesitate not to give a summary of their observations on the mean temperature of high northern latitudes.

Climate.

In Scoresby's *Arctic Regions* the mean temperature of the atmosphere of the Greenland seas, about Lat. 78° N., as deduced from 18 whale-fishing voyages, is for the month of April 14°·2 Fahr., for June 31°·4, for July 37°, or for the three warm months 26°·275, while, from fair data, he calculates the mean annual temperature of that latitude at no more than 17°·0. In his "Greenland Voyage" of 1822, alluded to by Humboldt, he found the mean temperature for the five months in which he navigated above Lat. 65° thus: April 32°·22, May 21°·42, June 32°·975, July 34°·30, August 35°·247, giving a mean temperature for the whole of 32°·231.

In Sir Edward Parry's two winter sojourns in the arctic regions we have still more decisive proofs of the fallacies of Mayer's formula. The following table of mean temperature is from the account of his third voyage, p. 71.

Months.	Melville Island, Lat. 74½°. 1819-20.	Winter Island, Lat. 66¼°. 1821-22.	Igloolic, Lat. 69⅓°. 1822-23.	Port Bowen, Lat. 73¼°. 1824-25.
October ...	− 6·46	+ 9 51	+ 9·79	+10·85
November	−23·60	+ 4·75	−22·37	− 5·00
December	−24·79	−15·94	−30·80	−19 05
January ...	−33·09	−25·96	−20·07	−28·91
February..	−35·19	−27·97	−23·41	−27·32
March	−21·10	−14·64	−22·75	−28·37
Mean ..	−24·04	−11·71	−18·27	−16·30

The mean temperature for all the months of the year at Port Bowen and its vicinity, was found to be no more than +10·01. In the perilous sojourn of four successive winters by Sir John Ross in Boothia Felix, Lat. 70°, we have the results of observations made continuously for each month of two successive years, 1830, 1831, and the annual mean temperature for each is +2·38 and +4·91.

In Captain Sir John Franklin's journeys to the shores of the American Arctic Ocean, the mean temperature of Fort Franklin, Lat. 65°·12, during two years is thus given—

		1825-26.	1826-27.
SPRING,......	March to May, ...	+14 43	+13·67
SUMMER,..	..June to August, ...	+50·40	
AUTUMN,..	September to November,..	+20·00	+20·25
WINTER,....	December to February, ..	−16·81	−16·40
	Mean...........	+11·46	

The mean temperature for each month of 1826 at Fort Franklin is thus given in his second expedition—

January..	−23·78
February	−12·70
March...	− 8·26
April...	+15·21
May..	+36·35
June..	+48·00
July...	+52·10
August..	+51·09
September......................................	+39·18
October...	+24·07
November	− 3·01
December..	− 7·42

A comparison of all these observations shows an increasing degree of cold as the longitude increases from the meridian of western Europe.

These observations on mean temperature in North America and its seas, compared with observations made in Europe, sufficiently show that some other coefficients than latitude and elevation above the sea must affect mean temperature. In fact, ever since meteorological observations began to be made with comparable thermometers, this became obvious; but it has been very apparent within the last few years, when we had obtained accurate registers of the heat of various parts of Asia, and of certain intertropical countries. The comparison of numerous such registers from various parts of the new and of the old continent, together with his own very extensive and accurate investigations of atmospheric temperature in various parts of the northern Temperate and Torrid Zones, proved to the illustrious Alexander von Humboldt, that no empirical formula will enable us to ascertain the law which regulates the mean temperature of the surface of our globe; and that we must collect the facts by multiplied and accurate observation in each locality. His philosophical views on this subject were first published in an admirable essay in the third volume of *Mémoires de la Société d'Arceuil.* He there showed that the very striking difference in mean temperature observed in large tracts of country under the same latitude, and at the same elevation above the sea, could not arise from the trifling influence of mere local peculiarities, but must depend on more general causes; as the form of continents, the nature of their surface, and especially on their size, position, and proportion to the adjacent seas.

As above two-thirds of the surface of our globe are covered by water, and as a transparent body like water and an opaque one like the land absorb and radiate the solar heat with very different facility, when falling on them at similar angles, it is obvious that the relative proportion of land and water at any part of the earth's surface must greatly modify the mean temperature of that region. The radiation of heat from rough and smooth surfaces towards a cloudless sky is very different; and the opaque, rough surface of the land will cool more rapidly than the surface of the sea by radiation. The comparatively smaller portion of the ocean covered with ice and snow than of the land will also produce some difference of mean temperature in places under the same latitude.

The difference between land and water in receiving and transmitting heat constitutes the difference between an insular and a continental climate. Water is not so soon heated by the summer sun as land, therefore the air over it is cooler in summer; and as the land cools faster than the sea in winter, the warmer sea air mitigates the cold of that season. Compare, for instance, the mildness of the climate of the British Isles with that of Sweden or the north of Germany, under the same parallels. This effect is further increased by the oceanic currents that carry the waters of warmer regions to our shores, in that remarkable deviation of the Gulf stream that sets across the Atlantic from Newfoundland to the western shores of Europe.

Laying aside hypothetical speculation, this distinguished philosopher undertook a very careful discussion of his own observations, and those of other meteorologists. His first difficulty was in obtaining the true *mean temperature* of any locality. He found that the usual method of taking half the sum of the maxima and minima of the day and night, or of the summer and the winter, would not give the true daily or annual mean temperature. But repeated observation led him to the important conclusion, "that the thermometer at the moment of sunset in every season indicates very nearly the daily mean temperature." Humboldt's observations on this point were chiefly made between 46° and 48° N. Lat.; and there is strong reason to believe that the same holds good in other latitudes—a circumstance which will mightily abridge the labour and greatly facilitate the acquisition of those important results. Humboldt finds that in western Europe the mean temperature of latitudes 30°, 40°, 50°, 60° are respectively 70°·5, 63°·1, 50°·2, and 40°·6 Fahr.; but in eastern America, under the same parallels, are 60°·9, 54°·5, 42°, 38°. Over the tropical Atlantic the lines of equal temperature are nearly parallel to the equator. On the other hand, proceeding east from Europe the lines of equal temperature bend toward the south; showing that Europe enjoys a higher mean temperature than either eastern America or eastern Asia.

Humboldt conceived the beautiful idea of representing on a chart of the world these variations of mean temperature,

by lines passing through places possessing the same annual mean temperature, which he denominates *isothermal lines*. A specimen of such isothermals is given in Plate CLXXIII.

He has given a summary of his observations on mean temperature in the following table for the northern hemisphere, divided into 6 isothermal bands. The degrees of heat are reduced from Humboldt's centigrade scale to that of Fahrenheit. This table not only gives the annual mean temperature, but that of the four seasons, considering December, January, and February as the three winter months. The prefixed asterisk (*) indicates those places where the mean temperature has been most accurately observed. The maxima and minima of the warmest and coldest months are also given:—

Humboldt's isothermal lines are drawn on what is termed an *equatorial* projection; and a first glance will show that they are neither parallel to each other, nor to the lines marking degrees of latitude. In Europe their summit is convex; but over Asia and America their summits are concave, and distinctly indicate the existence of two meridians of extreme cold in the northern hemisphere (the extremities of which will represent the poles of greatest cold), on both sides of which the mean temperature is higher than on those meridians. The poles of greatest cold would seem to be about 70° or 80° to the W. and the E. of the meridians of Paris and London, and about the 80° of N. latitude. This equatorial projection appears to have led Berghaus and others into the erroneous supposition that the isothermal lines formed isolated bands around each pole of greatest cold; whereas they form continuous bands, including both poles of cold, as is well seen in the isothermal charts of Professor Dove of Berlin, which are on the *polar* projection. (See Plate CLXXIV., which is copied from his work.)

The influence of oceanic currents on mean temperature was also pointed out by Humboldt; especially of his "Peruvian current," which carries the gelid waters from the frozen shores of the southern Victoria Land to the western coasts of Chile and Peru, and shows itself by the lower temperature of its waters far to the west of the Gallapagos Islands, in the equatorial Pacific Ocean; and of the longer known "Gulf stream" of the Atlantic, which brings the warm waters of the torrid zone along the eastern coasts of North America; and, where met by the polar current off the banks of Newfoundland, transports a portion of their warmth to the western shores of Europe, and often rejects on the western isles of Scotland, and the Orkneys, the seeds of the *Dolichos* or *Mucuna urens*, of the *Mimosa scandens*, and of other West Indian plants. The Gulf stream gives warning to the judicious mariner of his approach to the continent of America, by the superior temperature of its waters; and Humboldt mentions, that the Peruvian current has been found, off the coast of Peru, to have a temperature of no more than from 60° to 67° Fahr., while the sea just beyond the current raised the thermometer to 80°. Such currents, when extensive, must materially affect the heat of the superincumbent air; and thus we can understand how mean temperature must be locally affected by the direction of great oceanic currents.

It is well known that the heat of the atmosphere diminishes as we ascend mountains, and that, in every climate, there is a point where frost will be perpetual. The mean temperature of any place must therefore be materially affected by its level above the sea. This point of perpetual congelation may, in general terms, be said to diminish in altitude from the equator to the poles. At one time it was imagined that this diminution was uniformly according to latitude; and philosophers sought out a mode of calculating the point of perpetual congelation for each degree of latitude. The best known of these methods was that of Kirwan of Dublin. He conceived that if the point of congelation at the equator and its mean temperature were known, as well as the mean temperature of the given latitude, we could discover the point of congelation at that latitude by a simple equation. Thus, take the excess of both mean temperatures above the freezing point of water—and as this corrected mean temperature at the equator is to the point of perpetual congelation, so is the corrected mean temperature of the latitude to its point of congelation. But this ingenious speculation supposes a uniform depression of that point from the equator to the poles—which is not found to be the fact—and has led to as erroneous conclusions as the formula of other philosophers, who believed that the question might be determined by diminishing the mean temperature of any place by 1° Fahr. for every 300 feet of elevation. Upon these erroneous principles it has even been imagined that we could determine the height of mountains in any latitude, by the computed height of perpetual congelation in that latitude. Thus, when it was first announced that several peaks of the Himalaya range attained an elevation of from 25,000 to 27,000 feet, the accuracy of the observations was called in question; because in that latitude, it was contended that the snow line was not higher than 11,500 feet, and but a small part of these summits was veiled in perpetual snow; consequently their real heights could not possibly be more than a mile higher than the lower limit of snow, or in all from about 16,000 feet. But trigonometric measurements by several observers have since put their vast elevation beyond all doubt; and, what is still more remarkable, it has been proved that the snow line on their southern declivities lies 4000 feet lower than on their northern flanks. The explanation of this singular fact is supplied by Humboldt. The first cause is, that the air from the Indian ocean comes to the southern declivities of the Himalayas loaded with moisture which it deposits on the lofty summits with which it first comes into contact. But, in the second place, on the northern side of this vast aerial rampart, the powerful radiation of heat from the dry elevated table-lands of central Asia, situated below the almost parallel chains of the Himalayas, the Zungling and the Himmelsgebirge ranges of Klaproth, causes streams of dry warm air to ascend on the northern flanks of those mountains, and thus elevates the limit of perpetual snow. The happy effect of these circumstances has been pointed out by Humboldt—"Millions of men of Thibetian origin occupy populous towns, in a country where fields and towns would, during the whole year, have been buried in snow if these table-lands had been less continuous and less extensive."

Places which have the same annual mean temperature may differ materially in the difference of the mean temperature of their winter and summer. This, as well as the influence of the *cold meridians*, is well seen in the following table of Humboldt, in which he compares Europe with eastern America:—

Isothermal Lines of	Cisatlantic Region. Long. 1° W. and 17° E.			Transatlantic Region. Long. 58° to 72° W.		
	Mean Temperature.			Mean Temperature.		
	Winter.	Summer.	Dif.	Winter.	Summer.	Dif.
68°	50°·0	80°·6	21°·6	53°·6	80°·6	27°·0
59	44·6	73·4	28·8	39·2	78·8	39·6
50	35·6	68·0	32·4	30·2	71·6	41·4
41	24·8	60·8	36·0	14·0	66·2	52·2
32	14·0	53·6	39·6	1·4	55·4	54·0

The table shows the increase of the difference between the winters and summers, from the parallels of 28° and 30° to the parallels of 55° and 65° N. Lat. The increase or difference is more rapid in the transatlantic region; but it is remarkable that in both the divisions of the annual temperature between winter and summer is such that upon the isothermal line of 32° the difference of the two seasons is about double of that upon the isothermal line of 68°.

If, instead of the mean temperature of the seasons, we take that of the coldest and warmest month, and if we take places lying in the same climatic region and compare them with those in other regions, the difference becomes still more conspicuous; as, for instance, the region of western Europe with the region of eastern America, or of eastern Asia. The general principle in each region is that the differences increase from the equator to the pole; but, in certain situations this ratio is modified by the direction of the prevailing winds, and of oceanic currents, and by an insular climate. Thus, with us the breezes from the S.W., sweeping over the Atlantic, moderate the heat of our summer, and the severity of our winter; the oceanic current from Newfoundland certainly tends also to mitigate the vigour of our cold season; and from these causes, the climate of Britain is

more temperate than that of the same latitudes of continental Europe. The influence of similar causes in other places is indicated in the last column of this table.

The subject of isotherms has, since the publication of Humboldt's papers, been ably taken up by Professor Dove of Berlin, who has added much to our knowledge of the circumstances by which climate is modified. We have already noticed his polar projection of isothermal lines; and he has also given us a series of normal and abnormal isotherms in his very valuable publications on the distribution of terrestrial temperature. He has contributed not only extended annual isothermal charts, and for the four seasons, but also a series of isotherms for every month of the year. His observations on monthly mean temperature are the result of the discussion of registers kept at 700 stations. His fifth memoir contains those made at 230 new stations; the diurnal variations were collected from 29 stations; and since the publication of his fifth dissertation he has availed himself of the observations made at St Helena, the Cape of Good Hope, Madras, Australia, Hobarton in Van Diemen's Land, and Philadelphia in North America. The intervals between the stations have been filled up from the journals of 27 scientific voyages in the intervening seas. The scientific labour of Professor Dove has been immense, and the results highly interesting. He has also given illustrations of the annual variations of atmospheric pressure, and pointed out their bearings on climate. Dove's valuable charts were published by the Academy of Sciences of Berlin. A translation of this work by Mrs Sabine, with very valuable remarks by Colonel Sabine, has appeared in Britain, under the auspices of the British Association.

M. Dove has pointed out more clearly than had been previously done, the importance to determination of climate, of attention to the *annual* variations of atmospheric pressure; and expresses his surprise, that while *daily* barometric observations have been needlessly marked, so little attention has been paid to the *annual* fluctuations of the instrument. The *diurnal* variation had exhibited great regularity and distinctness in tropical America, and had attracted attention in Europe; but it seems strange that no remark was excited by the fact that barometric pressure was not found to diminish from winter to summer with increasing heat; and the *annual* variations scarcely excited attention.

The observations of Prinsep in Hindustan pointed out that there was a great difference between barometric variations in India and in tropical America; proving that there was in India a very marked *annual* variation; but it was erroneously supposed that this phenomenon did not extend beyond the tropics, and that it was an immediate consequence of the monsoons. The laudable investigations ordered by the Russian government made us acquainted with the meteorology of Siberia; and it was found, that north of the Himalaya, the supposed limit of the monsoon variations, the annual barometric variations are seen on a vast scale, extending even to the shores of the Icy Sea, a greatly diminished atmospheric pressure takes place in summer over the whole continent of Asia, and must produce an influx of denser air from all sides. This is the cause of the prevailing W. winds of Europe, the N. winds of the Frozen Ocean, and the E. winds that prevail on the E. coasts of Asia, and the S.W. monsoon of Hindustan. These facts, and their bearings on climate, have been discussed by Dove with much ability in several memoirs in the Berlin Transactions for 1852, and in Pogendorff's Annalen (58 and 77). The observations made by the British in India, the Cape of Good Hope, in Australia, and especially at Hobarton in Van Diemen's Land, he considers as of particular value; as enabling us to generalize atmospheric phenomena by a comparison of the southern with the northern hemisphere. The following is an abstract of his deductions from his multiplied investigations on this subject:—

1. Both in the north temperate and torrid zones the elasticity of aqueous vapour in the air increases with the temperature. In the region of the monsoons this increase is greatest near their northern limit, as in China and Hindustan. No such increase has been observed in the S. hemisphere. The curve of this elasticity has, however, a less convex summit in the region of monsoons than just beyond it; the elasticity continuing nearly the same throughout the rainy monsoon. Near the equator, the convex curve of the N. hemisphere is first flattened, and then transformed into the concave curve of the S. hemisphere; but in the Atlantic this transition takes place somewhat farther N. of the equator. The annual variation in the torrid zone is generally considerable at all places where equatorial currents prevail when the sun's altitude is greatest, and polar currents when the sun's altitude is least. It is inconsiderable wherever the direction of the wind is either comparatively constant throughout the year, or where its changes are opposite to that above described. In the last mentioned regions, the rate of decrease of the mean annual tension of aqueous vapour, with increasing distance from the equator, is more rapid than in the first class.

2. Over Europe and Asia the pressure of dry air decreases from the colder to the warmer months; and everywhere in the temperate zone has its minimum in the warmest month.

3. On comparing the annual variation of pressure of dry air in northern Asia and Hindustan with that of the Indian Ocean and Australia, we must conclude that something more takes place than a simple periodical transfer of the same mass of air in the direction of the meridian between the north and south hemisphere. From the extent of the phenomenon in the northern hemisphere, we must infer, that with the diminished pressure a *lateral overflow* takes place; and that this is the case is proved by the fact that, at Sitka, on the N.W. coast of America, the pressure of the dry air *increases* from winter to summer. It is improbable that the *overflow* takes place only to the east, but probably also to the west; and on this supposition the small amount of diminution of pressure of the dry air from winter to summer in Europe may arise, not solely from the moderate amount of the difference of

temperature in the hotter and colder seasons, but also from the *lateral afflux of air* in the upper regions of the atmosphere tending to compensate the pressure lost by expansion by heat. As at the northern limit of the monsoons at Chusan and Pekin the annual variation of pressure of dry air is not considerable, while, at the northern limit of the trade winds at Madeira and the Azores in the Atlantic it is very small, it is probable that there is in the torrid zone also a lateral overflow in the upper regions of the atmosphere, from the region of the monsoons to that of the trade winds.

4. From the combined action of the variations of aqueous vapour and of dry air we now derive immediately the periodic variations of the whole atmospheric pressure. As the height of the barometric column is the result of this combination, it may be considered as the result of two forces, one the pressure of dry air, the other the elasticity of vapour; and we can understand that, as with increasing heat the air expands and rises higher, and as its upper portion overflows laterally, while at the same time the increase of heat augments evaporation, and thus increases the quantity of aqueous vapour in the atmosphere, so it follows that the periodic variations of barometric pressure should not everywhere bear a simple obvious ratio to the periodic changes of temperature.

5. Throughout Asia, the increase with heat of the elasticity of vapour is never sufficient to compensate the diminished pressure of dry air; and the annual variation of barometric pressure is, therefore, everywhere represented, in accordance with the law of pressure of dry air, by a curve having its lowest point in July. The Russian observations at Yakoutsk, Udskoi, and Minsk, show this to be true up to the Okhotsk Sea on the east, and to the Frozen Ocean on the north. A tendency to these conditions is perceptible on the meridian of Petersburg, and becomes more conspicuous on approaching the Ural range. On the Caspian, and in the Caucasus, it is very distinctly marked; its limits run south from the western shores of the Euxine to Syria, Egypt, and Abyssinia, where it is found also to prevail. Towards the confines of Europe the general maximum is in September or October, the barometric pressure increasing rapidly from July to those autumnal months, towards the latter part of which a slight convexity or secondary minimum is observed; but beyond the Urals the curves become uniformly concave, with a single summer minimum and winter maximum, which holds throughout the rest of Asia. The little difference between the curve at Madras and Manilla, and the yet considerable curve at Nangasaki in Japan, show that the region in question extends beyond the eastern coast of Asia; at higher latitudes, it is bounded by Kamtschatka. The observations made by the British at Aden show that its western limit extends far in the direction of Africa.

6. In middle and western Europe the annual barometric variation is a decrease from the month of January to spring, and the minimum is in April; it then rises slowly but steadily to September, and rapidly sinks to November, when it usually has its minimum. In summer the increased evaporation more than counterbalances the loss by expansion, probably from a lateral overflow in the upper regions received from Asia. At Sitka the whole annual curve is convex, a result only found in Europe at considerable elevations, where it is the consequence of the expansion of the whole superincumbent mass of the atmosphere.

7. The region of great annual variation on the Asiatic side of the globe, when the monsoons prevail, extends much farther north in the northern than in the southern hemisphere; the variation has its maximum at Pekin, while at Hobarton, at nearly the same distance from the south side of the equator, it is trifling. The reverse is the case generally in the region of the trade winds, and in the Atlantic; for then the annual variation, though nowhere great, is decidedly more on the south than on the north of the equator, as is shown by the results of observations at the Cape of Good Hope, at St Helena, and Ascension Isle, Rio Janeiro, and Pernambuco, compared with the West Indies and the southern parts of the United States. Hence we find but small differences in annual variation between places in the southern Atlantic and southern Pacific in the same latitudes; while we find great inequalities between the N. Pacific and its eastern coasts and the very trifling variation observed in the north Atlantic. The explanation of this latter fact is evidently from the lateral overflow already noticed.

8. It is known that during the eruption of the Souffrière in St Vincent in 1812, volcanic ashes fell on the decks of vessels in large quantities more than 300 miles to the eastward of the volcano, and consequently were carried in the upper currents of the air in a direction against that of the trade winds; and in the eruption of the Coseguina, in central America, in January 1835, volcanic ashes not only fell in Jamaica, a distance of 800 miles to the *east*, but also fell on the decks of ships in the Pacific Ocean 700 miles *westward* of the volcano. The inference is, therefore, that in the higher regions of the atmosphere between the tropics, the aerial currents are not always in the same direction as the lower currents or *trades*, but sometimes is in the opposite, sometimes in the same direction. M. Dove has applied his comparison of the barometric relations of the region of the monsoons to that of the trade winds. Thus, if we suppose the upper portion of the air over Asia and Africa to flow off laterally, and if this take place suddenly, it checks the course of the upper or counter-current above the trades, and breaks into the lower current. An E. wind coming into a S.W. current must necessarily produce a rotatory movement of the air in a direction opposite to the apparent movement of the sun. A rotatory storm from S.E. to N.W. in the trade current would, on this theory, be the result of the encounter of two masses of air impelled against each other at many places in succession, as explained by Dove in his memoir on the "Law of Storms." Thus, the West Indian hurricanes, and the Chinese typhoons, occur near the lateral confines on each side of the great atmospheric expansion. The rarer occurrence of rotatory storms in the S. than the N. tropical Atlantic, arises from the more equal distribution of the periodic diminution of atmospheric pressure in the former than in the latter.

9. It is sufficiently obvious, that the irregular distribution of the land and the sea, which produces the abnormal variations in the form of the isothermal lines, is also the principal cause of the movements of the atmosphere. Thus the monsoons are but a modification of the trade winds, for the cause of which we must look beyond the N. tropic. The form of the Asiatic continent produces the great thermic expansion of the summer air over the interior of the old world, and presents all the characteristic marks of the region of calms, being a centre to which all the adjacent masses of air are drawn. Thus the subtropical atmospheric zone does not, as it were, uninterruptedly encircle the globe. The region over which the heated air ascends, does not therefore move N. or S. parallel with the sun's change of declination, but has rather a fluctuating movement, the fixed point of which is the West Indies, and the maximum of oscillation is over India. The northern excursion of this aerial movement is greater, as we have said, in the northern than in the southern hemisphere. The atmospheric relations of Europe, especially in summer, are therefore essentially of a secondary nature, and we must regard the small alteration in the atmospheric pressure over Europe in the course of the year as a secondary result, of which the explanation would have been exceedingly difficult, without a knowledge of the observations on atmospheric pressure from Asia and Australia.

Climate.

The horary variations of the barometer attracted the attention of Humboldt, and he gave the results in the volume of his travels published in 1825. *1st,* He proved that they are perceptible everywhere, to the height of 12,000 feet above the sea. *2d,* They consist of two ascending and two descending movements daily; the maximum in the morning is between 8½ and 10½ o'clock; the minimum of the afternoon between 3 and 5; the maximum of the evening between 9 and 11, and the minimum of the night between 3 and 5 o'clock. *3d,* In the temperate zone, the periods of maxima and minima are nearer to the passing of the sun over the meridian in winter than in summer by 1 or 2 hours. *4th,* In the torrid zone the times of maxima and minima are the same at the level of the sea, and at 8500 feet above it; but this does not appear to hold in the temperate zone. *5th,* The oscillations are very small about the time of maxima and minima. *6th,* For 15° N. and S. of the equator in the Atlantic and adjacent regions, gales, tempests, and earthquakes do not interrupt the periodicity of these diurnal variations, but on the Indian continent and coasts the rainy monsoons do so, though they do not on the Indian Ocean. *7th,* The diurnal variations are different in different months, and decrease as the latitude augments. The morning maxima is a little higher than that of the evening. *8th,* No observation yet made indicates a sensible influence of the moon on the oscillations of the atmosphere. Those attributed to the moon seem to be owing to the sun, not as a gravitating but as a calorifying body.

The following Tables show the Horary Variations between Lat. 25° S., and Lat. 55° N. from the Level of the Sea to 8500 feet of elevation.

TORRID ZONE.

Calculation of the effects of the sun's rays.

The variations of the superficial temperature of our earth are produced by the influence of solar heat. These superficial impressions are all produced, either directly or through the intervention of the atmosphere, by the action of the solar rays. It may be calculated from experiment, that the entire and unimpaired light of a vertical sun will communicate one centesimal degree of heat every hour to a sheet of water of a foot in thickness. Consequently, since the surface of a sphere is four times that of its generating circle, such a sheet of water, spread over

the whole of the globe, would receive six degrees of heat every day. But the very inferior capacity of the atmosphere for heat, being estimated as equal to that of a body of water about twelve feet in depth, if the aerial mass finally received and retained all the calorific impressions, it would every day have its temperature raised half a degree, and therefore augmented to $182\frac{1}{2}°$ in the course of a whole year. This annual accession of heat, however, is quickly dispersed by the mobility of the fluid medium, and gradually absorbed into the earth, or more quickly diffused through the waters of the ocean, which, besides, occupy at least three-fourths of the whole surface of our globe The luminous matter communicated by the incessant shining of the sun, whether received on the ground or intercepted in its passage through the air, would hence be capable of communicating one centesimal degree of heat to the body of the earth in the space of 1323 years; a quantity too small, perhaps, to be yet perceived, though its influence may be afterwards detected by very delicate observations.

It is easy to demonstrate, from the laws of optics, that the quantity of light which falls on a horizontal surface must be proportional to the sine of its obliquity. Hence the aggregate light received under the equator at either equinox is to what would accumulate during 24 hours, if maintained at its highest intensity, as the diameter to the circumference of a circle. This daily accession of heat, confined to the mass of atmosphere, would, therefore, in that climate and season, amount to 633,000 parts of a degree. At the pole itself, during the complete circuit of the sun in midsummer's day, the measure of heat would be about a fourth part greater, or 797,000 parts; the continued endurance of the sun above the horizon more than compensating for the feebleness of his oblique rays.

In general, the quantity of light received at any place from the sun in the space of one day is denoted by the product of the sine of the semidiurnal arc, or the distance from noon to the time of sunset, into the cosines of the latitude and declination, joined to the product of that arc itself into the sines of the latitude and declination: the latter part of the expression being considered as additive or subtractive, according as the declination lies on the same or on the opposite side of the latitude. Hence, at Edinburgh, in the latitude of 56°, the heat collected during one day at the summer solstice is 307,000 parts, but at the solstice of winter only 166,000.

If a current of air from the equator, having the ordinary temperature of 27°·5 C., were supposed to travel to the pole, from which an equal and contrary current would consequently flow towards the equator, each journey would transport 55° of heat. Between two and three such journeys performed every year would therefore be sufficient to disperse the whole accumulation of 138°. This only requires the existence of a wind advancing northwards at the rate of 46 miles every day. It is not necessary even that the wind should either continue permanent or blow directly north. The same effect would be produced if it were to blow indifferently to every point of the compass, and only at the rate of three miles an hour; a supposition which agrees tolerably with actual observation.

The circulation excited in the body of our atmosphere thus prevents the heat shed by the sun on different parts of the earth's surface from an excessive accumulation. In proportion as the equatorial regions grew warmer from the predominance of illumination, the polar wind would rush with more rapidity, till it had tempered the excess. This balance of the accession, and the consequent dispersion, of heat, has probably been long attained, and it now regulates the gradation of climates in successive latitudes.

The equilibrium of temperature preserved over the globe by the circulation of the atmosphere is not, however, very quickly produced. Hence the remarkable increase of heat which takes place during the summer months in the higher latitudes. But within the arctic circle, another powerful agent of nature is constantly tempering the inequality of the seasons. The vast beds of snow or fields of ice which cover the land and the sea in those dreary retreats, absorb, in the act of thawing or passing again to the liquid form, all the surplus heat collected during the continuance of a nightless summer. The rigour of winter, when darkness resumes her tedious reign, is likewise mitigated by the warmth evolved as congelation spreads over the watery surface.

Of the light received from the sun, a considerable portion is always detained and absorbed in its passage through the atmosphere. Even a vertical ray, shot through the clearest air, will lose more than the fifth part of its intensity before it reaches the surface of the earth. In most cases, the loss which light will suffer in the shortest transit through the atmosphere may be estimated at one-fourth of the whole. But the oblique rays must undergo a much greater absorption. If, from their slanting course, they have to encounter twice the number of aerial particles, their intensity must be reduced to $\frac{9}{16}$ths, or the square of three-fourths; and if they describe triple the vertical tract, only $\frac{27}{64}$th parts, or the cube of three-fourth, will reach the ground. In general, if the tracts of light follow an arithmetical progression, the diminished force with which it escapes and arrives at the ground will form a decreasing geometrical progression. To determine the train of aerial particles which the oblique rays of the sun must traverse in their passage through the atmosphere, is a nice problem, which requires a skilful application of the integral calculus. Without stopping to engage at present in the details of this intricate investigation, it may suffice to remark, that, in general, the length of the tract is nearly in the inverse ratio of the sine of the sun's altitude. But the following table, to every five degrees, is calculated from rigorous formulæ, the length of oblique tract being reduced to the standard of air uniformly dense. These quantities again are diminished in the ratio of the sine of obliquity, to express the calorific action which those enfeebled and slanting rays finally exert at the surface of the earth.

Sun's Altitude.	Measure of Atmospheric Tract.	Intensity of the Light transmitted.	Calorific Action at the Surface.

It hence appears that, even when the sky is most serene, only one-half of the sun's light can reach the surface of the earth from an altitude of 25°, or one-third from that of 15°, and that, if the obliquity of the rays were increased to 5°, no more than the twentieth part of them would actually be transmitted. The annual quantity of light which

Climate. falls may be computed as equivalent at the equator to a uniform illumination from an altitude of 17° 46′; and, in the mean latitude of 45°, and at the pole, the effects are the same as if the rays had respectively the constant obliquities of 13° 2′ and 7° 17′. Wherefore, under the most favourable circumstances, of 1000 parts of light transmitted from the sun, only 378 can, at a medium estimate, penetrate to the surface at the equator, 228 in the latitude of 45°, and 110 at the pole, of their oblique rays; but the shades received by a given portion of the surface are still less, being only 115, 51, and 14. In cloudy weather, the portion of light that can finally reach the ground will seldom amount to the third of those quantities; and when the sky becomes darkened with accumulated vapours, almost every shining ray is intercepted in its passage.

Influence of the sun's rays upon seas and lakes.

The light which at last gains the surface being there absorbed and converted into heat, is, in this form, profusely delivered to the ambient air, or more feebly conducted downwards into the body of the earth. But the rays which fall on seas or lakes are not immediately arrested in their course; they penetrate always with diminishing energy, till, at a certain depth, they are no longer visible. This depth depends, without doubt, on the clearness of the medium, though probably not one-tenth part of the incident light can advance five fathoms in most translucid water. The surface of the ocean is not, therefore, like that of the land, heated by the direct action of the sun during the day, since his rays are not intercepted at their entrance, but suffered partially to descend into the mass, and to waste their calorific power on a liquid stratum of ten or twelve feet in thickness.

But the surface of deep collections of water is kept always warmer than the ordinary standard of the place, by the operation of another cause, arising from the peculiar constitution of fluids. Although these are capable, like solids, of conducting heat slowly through their mass, yet they transfer it principally in a copious flow by their internal mobility. The heated portions of a fluid being dilated, must continue to float on the surface; while the portions which are cooled, becoming consequently denser, will sink downwards by their superior gravity. Hence the bed of a very deep pool is always excessively cold, since the atmospheric influences are modified in their effects by the laws of statics. The mean temperature of the climate is not communicated by these variable impressions; every change to warmth being spent on the upper stratum, while every transition to cold penetrates to the bottom, which thus experiences all the rigours of winter, without receiving any share of the summer's heat. But, if the beds of profound bodies of water remain perpetually cold, their surface undergoes some variety of temperature, and is generally warmer than the average weekly or monthly heat of the air.

These principles are confirmed by observations made on our own lakes, and strikingly exemplified in those of Switzerland, which have a depth proportioned to the stupendous altitude of their encircling mountains. It appears, from the careful observations of Saussure, that the bottoms of those majestic basins, whether situated in the lower plains or embosomed in the regions of the upper Alps, are almost all of them equally cold, being only a few degrees above the point of congelation. That accurate observer found the temperature of the Lake of Geneva, at the depth of 1000 feet, to be 42°, and could discover no monthly variation under 160 feet from the surface. In the course of July he examined the Lakes of Thun and Lucerne; the former at the depth of 370, and the latter at that of 640 feet, had both the temperature of 41°, while the superficial waters indicated respectively 64° and 68½° by Fahrenheit's scale. The bottom of the Lago Maggiore, on the Italian side of the Alps, was a little warmer, being 44° to the depth of 360 feet, while the surface was almost as high as 78°. Barlocci has since found that the Lago Sabatino, near Rome, at the depth of 490 feet, was only 44½°, while the thermometer, dipped at the surface, marked 77°.

Through the friendship of Mr James Jardine, civil engineer, we are enabled to give the results of his observations on some of the principal Scottish lakes, which, as might be expected from him, were conducted with the most scrupulous accuracy. The instrument which he employed for exploring the temperature at different depths was free from the ordinary objections; being a register thermometer, let down in a horizontal position, which could acquire the impression in not many seconds, and might be drawn up leisurely, without risk of subsequent alteration. It would appear that the variable impressions of the seasons do not penetrate more than 15 or 20 fathoms; that below this depth an almost uniform coldness prevails. Thus, in the deepest part of Loch Lomond, on the 8th September 1812, the temperature of the surface was 59°·3 of Fahrenheit; at the depth of 15 fathoms, 43°·7; at that of 40 fathoms, 41°·3; and from that point to about 3 feet from the bottom, at 100 fathoms, it decreased only the fifth part of a degree. Again, on the preceding day, the superficial water of Loch Katrine being at 57°·3, the thermometer, let down 10 fathoms, indicated 50°·6; at the depth of 20 fathoms it marked 43°·1; at the depth of 35 fathoms it fell to 41°·1; and on the verge of the bottom, at 80 fathoms, it had only varied to 41°. At the same place, on the 3d September 1814, the heat of the surface was 56°·4; at the depth of 10 fathoms, 49°·2; at that of 20 fathoms, 44°; at that of 30 fathoms, 41°·9; and at that of 80 fathoms, 41°·3.

Hence it is that, even in the northern latitudes, the deep lakes are never, during the hardest winters, completely frozen over. But if the same water be let into a shallow basin, it will, in a rigorous season, be chilled thoroughly, and converted into ice. This may even happen when spread above the surface of salt water, which is always considerably denser. Thus, frost takes no effect on Loch Ness, nor on the river of that name, which, in a rapid course of a few miles, discharges the surplus water into the sea. But in very severe winters a sheet of ice appears formed along the shore; the impressions of cold being almost wholly expended on the accumulation of fresh water, since the chilled portions of this, which continually descend, are stopped in their progress by the greater density of the recumbent sea-water.

The seas and the ocean itself obey the same law of the distribution of heat, only the difference of temperature experienced by sounding in the Mediterranean is less conspicuous than in the fresh-water lakes. Saussure found that the temperature at the bottom, in the Gulfs of Nice and of Genoa, at the depths of 925 and of 1920 feet, was the same, or 55°·8, the heat of the superficial water being about 69°. But the mean temperature, or that of the body of the land on the same parallel of latitude, is 59°. The smallness of the diminution here observed may perhaps be attributed to the effect of evaporation in such hot confined bays, the water at the surface being thus rendered salter, and consequently disposed, by its acquired density, to sink into the colder mass below.

In open seas, and in damper climates, the depression of temperature is greater in the inferior strata. This difference becomes augmented in proportion to the extreme variation of the seasons. Lord Mulgrave, on the 4th September 1773, in the latitude of 65° north, drew up water from the depth of 4100 feet, which he found to have the temperature of 40°, while the thermometer, dipped at the surface, stood, on the 19th June, at 55°. In the later experiments of Sir James C. Ross, the oceanic temperature at vast depths was found to remain stationary at about 40° Fahr. In the antarctic seas, in the year 1840, he found, when the surface temperature was 32°, at 400 fathoms it was 38°·8; at 600 fathoms it was 39°·8; and in December of 1841, in the S. Atlantic, when

the surface was at 53°, at the depth of 1050 fathoms, the register thermometer just indicated 40°, and sank no lower at greater depths. In the following year, he found, a little to the north of Ascension Island, when the surface temperature was 42°, at 600 fathoms it stood just at 40°, and sank no lower when let down to the enormous depth of 4600 fathoms, 27,600 feet, or above 5 miles. In the still deeper soundings of Captain Denham in 1852, at a depth of 46,236 feet, or above $8\frac{3}{4}$ miles, the temperature was still 40°.

A like gradation of temperature is produced by the alternating influence of the seasons in deep and stagnant masses of air. When this active fluid is confined in profound caverns, opening to the sky without being much exposed, and either perpendicular or gently inclined, its lower strata become intensely and permanently cold. The mild air of summer floats motionless at the mouth of the pit; but, in winter, the superior air, cooled many degrees perhaps below the freezing point, and therefore greatly condensed, precipitates itself continually to the bottom.

This fact takes place in most caverns, and in draw-wells which are left uncovered. Saussure found, on the 1st of July, when the thermometer in the shade stood at 78° of Fahrenheit, that a cave in the Monte Testaceo, a small hill in the vicinity of Rome, formed entirely by the enormous accumulation of broken pottery, had the temperature of 50°; and two other caves in the same porous mass were cooled to 44°. On the 9th July, when the external air was at 61°, the cave of St Marino, at the foot of a sandstone hill about 2080 feet above the level of the sea, indicated only $44\frac{1}{2}$°, which is 8° below the mean temperature of the soil in that situation. In the grotto of Ischia, and in the caves of Cesi and of Chiavenna, the thermometer marked likewise $44\frac{1}{2}$°; but in the caves of Caprino, on the borders of the Lake of Lugano, it stood at different times of the year at 37° and 42°; and in those of Hergisweil, near Lucerne, the heat of the interior on the 31st of July was only $39\frac{1}{2}$°.

But this phenomenon is still more striking in certain peculiar circumstances. The famous Swedish mine of Dannemora, which yields the richest iron ore in the world, presents an immense excavation, probably two or three hundred feet in depth. On the occasion of some repairs which suspended the usual labours, the basin appeared some years since full of water, with huge blocks of ice floating in it. The silver mine of Königsberg, in Norway, has for its main shaft a frightful open cavern, perhaps three hundred feet deep and thirty feet wide, of which the bottom is covered with perpetual snow. Hence, likewise, on the sides of Ætna and of the mountains in Spain, the collected snows are preserved all the year in caves and crevices of the rocks, from which natural stores the muleteers carry down, during summer, to the villages and the cities of the plain, a material so necessary to comfort in those parched climates.

Absolute quantity of heat the same at every elevation.

Such is the disposition induced in a confined column of air; but in a free atmosphere the gradation of temperature is exactly reversed, the lower strata being invariably warmer than the upper. This most important fact in meteorology and physical geography was thought sufficiently explained, in the infancy of physical science, from the proximity of the heat supposed to be reflected by the surface of the earth. But it were idle to attempt any serious confutation of such crude ideas. The true cause of the cold that prevails in the higher regions of the atmosphere is undoubtedly the enlarged capacity which air acquires by rarefaction. From the unequal action of the sun's rays, and the vicissitudes of day and night, a quick and perpetual circulation is maintained between the lower and the upper strata; and it is obvious that, for each portion of the air which rises from the surface, an equal and corresponding portion must likewise descend. But that which mounts up, acquiring an augmented attraction for heat, has its temperature proportionally diminished; while the correlative mass falling down, carries its share of heat along with it, and, again relaxing its attraction, seems to diffuse warmth below. A stratum at any given height in the atmosphere is hence affected both by the passage of air from below and by the return of air from above, the former absorbing a portion of heat, and the latter evolving it. But the mean temperature at every elevation is on the whole still permanent, and consequently those disturbing causes must be exactly balanced, or the absolute measure of heat is the same at all heights, suffering merely some external modification from the difference of capacity in several portions of the fluid with which it has combined. That temperature is hence inversely as the capacity of air having the rarity due to the given altitude.

Investigation of the increased capacity of rarefied air.

It only remains, therefore, to discover the capacity of air, or its attraction for heat under successive pressures, or at different degrees of rarity. But this problem requires a very nice investigation, and appears incapable of being resolved by any direct procedure. If the elaborate experiments of Dr Crawford and others on the capacity of air in its ordinary state gave such erroneous results, what hope could be formed of ascertaining even its minute shadings, by any similar plan of operation? But, independently almost of any theory, a simple method occurs for conducting this research. A delicate thermometer, suspended within the receiver of an air-pump, indicates a decrease of temperature as the process of rarefaction advances; and, on stopping this operation at any stage, the thermometer will slowly regain its former state. If now, when the equilibrium is restored, the air be suddenly readmitted, the dilated portion which had remained in the receiver liberates the heat absorbed by it during the progress of rarefaction. The thermometer accordingly rises quickly through a certain space, then becomes for a short while stationary, and afterwards slowly subsides. But the instrument does evidently not measure the whole of the heat thus evolved; a great part of it being spent in warming up to the same point the internal surface of the receiver. This action, however, is merely superficial, since its effect appears to be momentary. Consequently, the internal surface of the receiver, with that of the plate on which it stands, as penetrated by the sudden impression to a certain very minute depth, forms a constant film of matter, which as well as the body of air itself, draws its supply from the extricated heat. Under the same receiver, therefore, although the air will not seize the whole of the heat disengaged in the act of admission, it must always retain a proportional share of it. A series of experiments, at successive degrees of rarefaction must hence discover, if not the absolute, yet the relative changes of the air's capacity for heat.

Details of the experiment.

To institute this inquiry with the desired success, an excellent and powerful air-pump was used, having a receiver of the very largest dimensions, of an oblong spheroidal form, approaching, however, nearly to the globular, and with a narrow bottom. The apparatus being placed in the middle of a close room, which had a steady temperature, a thermometer with a slender stem, open at top, and a small bulb of extreme sensibility, was fixed in a vertical position, a few inches above the centre of the plate. Having replaced the receiver, and allowed it to stand some time, one-fifth of the air was now extracted from under it; and, after a considerable interval, the cock was suddenly opened, to restore the equilibrium; when the mercury of the thermometer, which had been stationary, mounted up very rapidly 3·0 centesimal degrees, from which point it afterwards slowly descended.

The temperature of the room having been regained, two-fifths of the air in the receiver were then extracted; and after some lapse of time, the external communication being repeated, the thermometer rose instantly 5·3 centesimal de-

Climate.

grees. On extracting three-fifths of the internal air, the corresponding ascent of the thermometer, at the restoration of the equilibrium, was 7·0 of those degrees; and, when the contents of the receiver had been rarefied five times, the heat evolved, on the re-admission of the air, amounted to 8·0 degrees. The rate of progressive effect was thus evidently diminishing. On pushing the rarefaction as far as it was really practicable, or till the residual air had become rarefied about 300 times, the change indicated by the thermometer did not reach to more than 8·3.

But, to determine the absolute quantity of heat which is disengaged in the transition of air from a rarer to a denser state, it becomes necessary to ascertain what part of it was consumed on the sides of the receiver. By varying the size of the receiver, and consequently altering the proportion between its surface and its contents, some light may be thrown on this question. Another similar receiver was therefore provided, having half the former dimensions; and with this the same set of experiments was repeated. Its included air being reduced successively to the density of four-fifths, three-fifths, two-fifths, and one-fifth, and then rarefied as much as possible, the thermometer mounted each time through the shorter spaces of 1·8, 3·2, 4·2, 4·8, and finally 5·0 centesimal degrees. These quantities evidently follow the same proportion as the former, of which indeed they are only three-fifths. But the smaller receiver, having, under the fourth part of the surface of the larger, only the eighth part of its contents, exposes comparatively twice the extent of surface. The rise of temperature which its included air exhibits must consequently be the same as what would have obtained within the larger receiver, if, while its capacity remained the same, its surface had been actually doubled. If we suppose the air to hold one part of the heat, while two parts and four parts are respectively expended on the insides of the receivers, the results would correspond with observation; for the whole quantity evolved being in both cases the same, the air under the larger receiver would retain one-third, and under the smaller receiver only one-fifth; the impressions being thus in the ratio of five to three. The same conclusion may be obtained somewhat differently. If the heat spent on the inside of the larger receiver had been spread over twice the surface, it would have raised the temperature only 1°·5; but this mounted really to 1°·8, and therefore the difference ·3 was the effects of 1°·8 derived from the contained air. Of the heat thus shared between the air and the doubled surface, one part was hence retained and five communicated. Consequently, to obtain the true results, it is only necessary to multiply the second set of quantities by five, or the first set by three. If no waste, therefore, took place against the inside of the receiver, the heat evolved in the passage of air from the densities of four-fifths, three-fifths, two-fifths, one-fifth, and extreme rarefaction, to its ordinary state, would be 9, 16, 21, 24, and 25 centesimal degrees.

Inferences.

It is not difficult to discover the law of this progression. They are obviously formed by the successive addition of the odd numbers 9, 7, 5, 3, and 1; and are, consequently, the excesses of the square of 5 above the squares of 4, 3, 2, and 1. Wherefore, if the square of the density be taken from unity, the remainder, multiplied by 25, will express in centesimal degrees the rise of temperature which accompanies the return of the air to its ordinary state.

The numbers thus obtained, however, do not still express the final results. If the restoration of four parts of the air included under the receiver to their usual density, disengage heat sufficient to raise the temperature of the whole five parts 9 degrees, its real measure must have been $11\frac{1}{4}$ degrees, or the former augmented in the ratio of 4 to 5. For the same reason, if three-fifths, two-fifths, and one-fifth of the air in the transition of density, evolve portions of heat which would elevate the temperature of the mass 16, 21, and 24 degrees, the actual quantities are $26\frac{2}{3}°$, $52\frac{1}{2}°$, and 120°, or those numbers multiplied by 5, and divided by 3, 2, and 1.

General conclusion.

These conclusions are easily reduced to formulæ. Let θ denote the density of the air, and $25\,(1-\theta^2)$ will express, in centesimal degrees, the elevation of the thermometer which would follow the re-admission of the air, if none of the heat were spent on the inside of the receiver. Consequently, $25\left(\frac{1-\theta^2}{\theta}\right)$, or $25\left(\frac{1}{\theta}-\theta\right)$, will exhibit on the same scale the whole quantity of heat evolved in the restoration of density. The last formula is extremely simple, implying that 25, multiplied into the difference between the density of air and its reciprocal, will represent the measure of heat due to the change of condition. This result may be either additive or subtractive; it may express the heat emitted in the condensation of air, or the heat absorbed during its opposite rarefaction.

Application of the formula.

Thus, the heat extricated from air which has its density doubled is $25°\,(2-\frac{1}{2})$, or $37\frac{1}{2}°$; and the same quantity is withdrawn, either when this air recovers its former density, or when air of the ordinary state expands into double its volume. Hence the copious heat extricated by the sudden compressiou of air. If it were condensed thirty times, the heat discharged would amount to $25\left(30-\frac{1}{30}\right)$, or 749°, which is more than sufficient for the inflammation of fungous or soft substances. On this principle are constructed the pneumatic matches invented by Mollet of Lyons, which produce their effect by the momentary action of a small syringe.

But, to discover the relative capacity or attraction which air of a given density has for heat, it would be necessary to know the extent of the natural scale, or the position of the absolute zero. The conclusions, however, from different data, are not very constant; yet several experiments appear to fix nearly the point from which the infusion of heat commences at 750 centesimal degrees below congelation. On this supposition, therefore, air which is rarefied thirty times has its capacity doubled, the heat contained in it being dilated only fifteen times. For the same reason, air sixty times rarer than ordinary acquires a triple attraction for heat, which, in this union, becomes attenuated only twenty times. But these inferences are merely speculative, and the law of the gradation of temperature in the atmosphere is quite independent of the existence of an absolute term of heat.

The last formula now investigated has been already laid before the public, without any explication, however, or indeed indication, of the process by which it was discovered. The experiments on which it rests were begun many years since, and have been repeated with every precaution. But the mean results only are retained; and, for the sake of simplicity, a few slight modifications have been introduced, to adapt the apparatus to more convenient proportions. Though it was impossible to blow a receiver that should have *exactly* half the dimensions of another, nothing seemed easier, from the general mode of investigation, than to apply the minute corrections which any small deviations of size or form required. The mixture of obscure and intricate computations has been thus avoided.

Since the absolute quantity of heat contained in every part of any vertical column of the atmosphere has been shown to remain unchanged, this formula must likewise represent the diminution of temperature in the higher strata corresponding to the decreased density of the air at different elevations. The same formula will determine the measure and gradation of this effect. Reckoning the density of the air at the surface of the earth unity, the difference between the density at any given altitude and its reciprocal, being multiplied by 25, will express the mean diminution of tem-

perature in centesimal degrees; or if 45 be employed as the multiplier, the product will exhibit the same result in degrees of Fahrenheit's scale.

This very simple deduction from theory is amply confirmed by numerous and extensive observations. But a few leading facts will perhaps be deemed sufficient for exemplification.

Examples of the application of the formula

According to Lasius, the same barometer which, at Goslar, an ancient town seated in the bosom of the Hartz Forest, stands at 29,500 inches, would fall to 26,444 on the top of the Brocken, in that mining district. This gives ·896 for the density of the air on the summit, the reciprocal of which is 1·116; but $1·116-·896=·22$, and $·22 \times 25° = 5°·5$, the calculated difference of temperature. The actual difference is very nearly the same, being only 5°·2; as we had once an opportunity ourselves of observing, having found the temperature of a copious spring at Goslar to be eight centesimal degrees, while that of the noted Hecken-Brunnen, or *Witch-Well*, on the summit of the Brocken, was only 2°·8.

Saussure, whose accuracy always inspires confidence, found that, while at his villa of Conche, near Geneva, the barometer stood at 28·500, another similar instrument fell to 25·165 on the top of the mountain of Nant Bourant. The diminished density of the air at this elevation was, therefore, ·890; the difference between which and its reciprocal 1·123 being multiplied by 25°, gives 5°·82. But a thermometer buried a whole night at two feet deep in that lofty station marked only 12°·75, while it indicated 6°·25 more, or 19°, a few days afterwards, when sunk to the same depth at Conche. The discrepancy here is thus less than half a degree.

to the temperature of the ground;

On the top of a higher mountain, the Chapieu, the same observer found the ground, at a depth of two feet, to be colder by 6°·44 than at Conche; but the corresponding density of the air and its reciprocal were ·872 and 1·147; consequently, $2° \times ·275 = 6°·87$.

While the barometer at Conche stood at 28·500 inches, the mercurial column was only 19·836 inches on the summit of Mont Cervin, a still loftier mountain. The density of the air at this elevation was therefore ·696, which being taken from its reciprocal 1·437, leaves ·741 to be multiplied by 25°, including 18°·52 as the diminution of temperature. The actual medium difference ascertained from corresponding thermometrical observations, made at depths in the ground from one to three feet, on the top of Mont Cervin and at Conche, was 18°·25, almost exactly the same.

Such is the nice agreement on the whole, between theory and observation, with regard to the decrease of the mean temperature in the higher regions of the atmosphere. This gradation of cold varies, however, to a certain extent with the seasons. Since the heat derived from the sun is chiefly accumulated at the surface of the earth, the changes of temperature which take place through the year in the elevated strata of our atmosphere must evidently be less than what are experienced below. The lofty tracts of air, remote from the primary scene of action, preserve nearly an equable temperature, and scarcely feel the extreme heat of summer or winter's frost. In ascending the atmosphere, the decrease of warmth is hence more rapid in the fine season, and more slow in the darkened period of the year. In many places, it will not be far from the truth, perhaps, to assume 30° for the multiplier during the summer months, and only 20° during those of winter.

and to that of the atmosphere.

Thus General Roy, a diligent and experienced observer, found, in the month of August, the air on the top of Snowdon was, in the course of a whole day, at an average, 7·2 centesimal degrees colder than on Caernarvon quay; but the difference between the density at that elevation and its reciprocal, or between ·878 and 1·139, being only ·261, would require nearly 28 for the multiplier.

In the early part of September, the same observer noticed the centesimal thermometer to stand 10 degrees lower on the top of Ben Lawers than at Weem, the relative density of the air at that height being ·868. The difference from its reciprocal is ·284, which would hence require to be multiplied by 35 to give the actual diminution of temperature.

Again, Saussure found, on his visit to Mont Blanc, the air on its summit to be 31 centesimal degrees colder than at Geneva. The relative density was ·592, which being taken from its reciprocal 1·689, leaves 1·097; consequently the multiplier required is 28.

This ingenious philosopher passed several days encamped on the Col du Géant, where he found, from the mean of eighty-five observations, the temperature of the air to be only 4°·54, or 20°·3 colder than at Geneva; but the relative density of that elevated stratum and its reciprocal were ·704 and 1·420; the difference of which, or ·716, would require to be multiplied by $28\frac{1}{2}$ to indicate the diminished temperature.

The observations made on the decreased temperature of the higher regions of the atmosphere by the ascension of balloons, appear generally to indicate rather a slow rate of diminution; but it should be recollected that those daring aerial flights have seldom been performed except in the fine season of the year. Besides, the car, the balloon, and its cordage, will not immediately acquire the temperature of the elevated strata, but continue for a considerable time to diffuse a sensible portion of heat. A memorable example, however, is entirely conformable to the general principle. Charles, the first who ascended the atmosphere by means of a balloon filled with hydrogen gas, found, on the 1st of December 1783, the thermometer depressed 11 centesimal degrees at the greatest elevation, the column of the barometer having sunk from 29·24 to 20·05 inches. This would require a multiplier less than 20.

Origin of glaciers.

The curve of perpetual congelation must evidently rise higher during the tide of summer, and again descend in the winter months, thus oscillating between certain limits of elevation. The intervening belt is narrow under the equator; but it enlarges to a very considerable extent in the higher latitudes. On the breadth of this zone, where frost holds a doubtful reign, depends the formation of *glaciers* along the flanks of the snowy mountains. The fields of snow which are alternately melted and congealed, become at last changed by this process into ice, often grouped and fashioned by such irregular action into the most fantastic shapes. In its native seat, this icy belt acquires continual additions to its height, till the accumulating pressure urges it downward, and at last precipitates its fragments to a lower level. In its new position, below the inferior boundary of congelation, the enormous pile suffers, on the whole, a very gradual thaw, which is sometimes protracted for several centuries. Meanwhile, in the higher magazine, another belt is again slowly collecting, which will in due time repeat the succession, and maintain the perpetual circle of production and decay.

Within the tropics, the zone of undecided frost is so very narrow, that scarcely any trace of a glacier has been ever observed. But as that zone enlarges in the higher latitudes, the appearance of vast glaciers constitutes a very striking feature in the aspect of the lofty mountains. They occur frequently along the sides of the Pyrenees, but they are still more conspicuous in the recesses of the central chain of the Swiss Alps. Glaciers are likewise seen as far north as the verge of the arctic circle. Along the western shore of Norway and the coast of Lapland, stretching onwards to the promontory of the North Cape, huge masses of glacier ice descend from the cliffs, or against the precipitous sides of the mountains, almost to the surface of the ocean.

Climate is affected by the intensity of solar light, or what

Climate.

has been termed *insolation*. This influence was not much remarked until of late years. The effect of light on the colour of plants, indeed, attracted the attention of philosophers in the last century, especially of Ingenhouz and Sennebier; and practically, the effect of *etiolation*, or blanching of vegetables growing in darkness, was known to gardeners. But the effects of light on animals attracted little attention. Some had remarked the comparative rarity of bodily defects in the natives of hot climates where the light is strong; but the experiments of Dr W. F. Edwards on tadpoles proved that light exerts considerable influence on the animal frame. He showed, that if one portion of the same brood be exposed to light, while another portion was suffered to live in darkness, while every other circumstance was the same in each, that the change to the perfect frog took place far sooner in those exposed to light than in those kept in darkness, the latter arriving almost to the size of their parents before the change took place. Instruments, therefore, for measuring the degree of solar light form now part of a meteorological apparatus. Two instruments of this sort are chiefly employed, the actinometer and the photometer of Professor Leslie. The former consists of a thermometer with a large oblong bulb, and filled with a dark coloured fluid. As it has no fixed point, it is reduced for each observation to a zero by means of a screw acting on the elastic extremity of the bulb, formed of a slip of caoutchouc; the instrument, in a case covered by a glass, is exposed to the direct rays of the sun, and its rise then noted. It affords comparative indications of the intensity of solar light.

Photometer.

For measuring the intensity, or at least the calorific action of light, no instrument is so finely adapted, by its peculiar delicacy, as the *Photometer*, which consists of a *Differential Thermometer* inclosed in a thin pellucid case, and having one ball made of black and the other of clear glass. It will besides admit of some variety in its form and construction, and may be rendered on the whole very commodious and portable. Yet, owing to a combination of circumstances, this elegant instrument has only been partially and reluctantly admitted; and the philosophic world has still to discharge an act of justice, by receiving it into the favour and distinction which it so well deserves. Some, indeed, affecting to display superior sagacity, have taken the trouble to remark that it was only a species of thermometer, and not strictly a photometer, since it measures heat and not light. But what does the thermometer itself indicate, except *expansion?* As heat is measured by the expansion it occasions, so light is determined by the intensity of the heat which, in every supposition, invariably accompanies it. What other mode, after all, could be imagined for detecting the presence of light? How can an unknown quantity be expounded, but in terms of one already known?

Importance of that instrument.

The photometer is adapted for a variety of important meteorological researches. If such instruments, in the hands of skilful observers, had been dispersed to the remote regions of the globe, we should ere now have obtained a body of precise facts, highly instructive in themselves, and calculated to illustrate the nature of different climates. Meanwhile, we shall endeavour to state the general consequences which may be drawn from even a scanty range of photometrical observations.

The direct and absolute action of the sun's rays on the photometer, at the elevation of 30°, may be reckoned in this climate at 120 millesimal degrees. The effect is produced by the incidence of a pencil of light, which has for its base a circle of the same diameter as the black ball, but modified and regulated in its amount by the subsequent dispersion of the accumulated heat from the whole surface of the sphere, which is four times greater than that of the generating circle. If a thin disc were, therefore, substituted instead of the ball, and presented to the perpendicular rays of the sun, the impression would be doubled, or raised to 240°; or if the emission of heat from the posterior surface of the disc were prevented, the calorific effect would amount by this accumulation to 480°, or 86° on Fahrenheit's scale. Such is the rise of temperature which a dark surface of dry mould, sloping at an angle of 30°, yet exactly fronting the sun, might acquire under a diaphanous shell of glass, if scarcely any portion of the heat were supposed to be conducted downwards into the mass of the earth. But since the rays of light which traverse the atmosphere under an obliquity of 30° have, in comparison with perpendicular beams, their force diminished in the ratio of 750 to 563; the action of a vertical sun, through a thin capsule of glass, might heat up a dark horizontal surface, 113° by Fahrenheit's scale. On removing the glass cover, this effect, in a calm still air, would be reduced about two-thirds, or to $75\frac{1}{2}$°.

Calorific action of the rays in different circumstances.

It is obvious that the accumulated effect of the incident rays much increase in proportion as the conducting power of the medium is diminished. Hence, at an elevation of three miles and a half, where the density of the atmosphere is reduced to one-half, the heat communicated would, on this account alone, augment from $75\frac{1}{2}$ to 83 degrees. But the effect would be further increased, from the smaller absorption of heat in its passage to the surface. Under the equator, the whole accumulated action would, therefore, amount to 96 degrees. All travellers, accordingly, complain of the scorching rays which the sun darts from a dark azure sky on the summits of lofty mountains. Yet the contrast is more striking in the higher latitudes. Thus, in the middle parallel of 45°, the action of the sun at the summer solstice would excite a heat of 69° at the level of the sea, and of 90° at an elevation of three miles and a half; but at the winter solstice it would communicate only 17° below, and 46° at the altitude assumed. Saussure was accordingly very much struck with the force and brilliancy of the sun-beams on the top of Mont Blanc.

It might easily be computed that, on the supposition of a perfect calm, the surface of the earth under the equator, will, at the medium of a year, have its temperature raised 12°; and that, in the latitude of 45°, the mean annual impression would be only 5°. But, of the whole of the light received, the calorific action on a black mould, whether emitted from the sun or shed indirectly by the sky, may be deduced from the indication of the photometer. It is only required to diminish the power of the sun's rays in the ratio of the sine of their obliquity, and to reduce the action of the light reflected from the canopy of clouds to one-half, or what is due to the medium inclination of 30°, then to multiply the sum of these quantities by eight, and divide by three, or to take two-thirds of the quadrupled effect. Thus, suppose, while the sun's altitude is 40°, that the photometer marks 155°, which it very seldom ever reaches in this climate, and that it indicates only 20° if merely screened from the direct action of the sun. Now, 155° multiplied by the sine of 40° makes 87°·8, which is augmented to 97°·8 by the addition of the half of 20°; and this number again being increased in the ratio of 3 to 8, gives finally 261 millesimal degrees, or 47° on Fahrenheit's scale. When the sun is obscured in clouds, the reflected light, from a dappled sky, will sometimes in summer affect the photometer to the extent of 50°. This corresponds to a heat of 16° of Fahrenheit communicated to the ground. During the fine season the photometer seldom in cloudy weather indicates less than 15°, which is equivalent to an impression of 6° on the embrowned surface of the earth. While the sun is enveloped in clouds, if the rest of the sky assumes a fine azure hue, the photometer will only mark 10°. But in the gloomy days of winter, the minute portion of light which pierces through the congregated mass of clouds will scarcely affect the photometer 5°, or excite a heat of 2° by Fahrenheit on the ground.

These augments of temperature are communicated to the ground unimpaired, only in the case, however, of a perfect calm. The agitation of the atmosphere will scatter the heat before it has accumulated. When the wind creeps along the surface of the earth at the rate of eight miles in the hour, it diminishes the calorific action of the light from the sun and from the sky one-half; but if it sweeps with a velocity of 16, 24, or 32 miles in the hour, it will reduce the whole effect successively to the third, the fourth, or the fifth of its standard. The impression made on the ground seldom, therefore, exceeds the third part of the computed measure, and often will not amount to one-fifth.

Effect on the ground diminished by wind;

The simplest and most accurate method of examining the temperature acquired during the day on the surface of the earth, is to employ a differential thermometer of the pendant kind, about one or two feet in length, and having its lower ball surmounted by a small cylindrical cavity supporting the coloured liquor. This instrument being suspended or held in a vertical position, the lower ball resting on the ground, will evidently mark, by its movable column, the difference between the temperature of the surface and that of the ambient air. In this way, we have found, during the summer months in this climate, that the ground was, by Fahrenheit's scale, generally two or three degrees warmer than the air near it in cloudy weather, and perhaps ten or fifteen degrees warmer when the sun shone powerfully upon it. But, under similar circumstances, the effect varies very considerably, according to the nature of the surface. While fresh ploughed land, for instance, indicates an increased temperature of perhaps 8°, a grass plot close beside it will scarcely show a difference of 3°. Nor is this distinction owing to any greater absorption of light by the black mould; the reflection from the surface, in both cases, being extremely small. A thin layer of hay, whether spread on the naked soil or on the green turf, will betray the same diminished effect. The fibres of the grass exposing a multiplied surface to the contact of the air, the greater portion of the heat is hence dissipated before accumulation. A corresponding effect has been remarked with respect to the impressions of cold. Thus, in the neighbourhood of Edinburgh, after a long tract of rigorous weather, the frost was found to have penetrated thirteen inches into the ground in a ploughed field, but only eight inches in one piece of pasture ground, and four inches in another. But, in some of the streets of that city, the frost had descended even below two feet, so as to begin to affect the water-pipes. The greater density and solidity of the pavement had no doubt conducted the frigorific impressions more copiously downwards, while the loose and spongy blades of grass had mostly scattered and wasted those impressions in the open field. This consideration, it is obvious, might lead to very important practical results.

and varies with the quality of the surface.

The unequal action of light at the surface of the earth, whether produced by the various obliquity of the sun's rays, the different inclination of the horizon, or the alternating succession of day and night, is attempered, we have seen, by the actual flow of the heated portions of the atmosphere. Between the poles and the equator, a perpetual circulation of air is maintained, which confines the accumulating effects of heat within narrow limits. The prevalence, on the whole, of northerly winds in this hemisphere during summer, and of southerly winds in winter, tends likewise to mitigate the extreme impressions of hot and cold. But a current of warm air, excited at first by the presence of the sun, continues to rise from the ground, and occasions the descent, therefore, of an opposite current of cold air, which, as the equilibrium of temperature is not soon restored, may be protracted through a great part of the night. The combined influence of these currents is hence continually exerted in cooling down the surface of the earth; but their activity being the greatest while the solar beams fall most copiously, the accumulation of heat is checked in little more than an hour after mid-day, while its further dissipation is prolonged through the whole of the night, sun-rise being generally the moment when the ground is coldest.

Circulation of air between the poles and the equator;

Such a concatenated system of aerial currents might hence appear sufficient to explain the gradation and general balance of temperature which prevails on the surface of our globe. An horizontal stream of air must evidently cause the flow of an opposite one, since the action must be the same on every part of the same parallel of latitude. The difference of the temperature of the surface from that of the ambient air will maintain the constant play of an ascending and a descending current. In clear and calm weather, this interchange between the higher and lower strata of the atmosphere will be the most vigorous, owing then to the concentrated impression of the sun-beams. The perpetual commerce maintained in our atmosphere by the medium of these combined horizontal and vertical currents, forms no doubt an essential part of the system which attempers the constitution of this globe. But it is not the only mode by which nature seeks to preserve the harmony of her productions; and recent discovery has detected the existence of another auxiliary principle, extremely active, of most rapid and extensive influence, and continually at work, though subject to various modifications. To understand rightly, however, the operation of this principle, it will be necessary to recal the chief facts which have been disclosed relative to the propagation of heat.

Regulates the temperature of the globe.

It is well known that, though partial causes may disturb the equilibrium of temperature among bodies, there is a constant tendency to restore it again. Yet heat still remains in the state of combination, without ever assuming a distinct form. Its balance is, therefore, maintained by a very different process from that which establishes the equilibrium between the several communicating parts of a liquid. The substratum of heat is not passive, nor do the calorific particles themselves merely flow from their redundance towards another situation where they happen to be deficient. But since the presence of heat is invariably accompanied by corpuscular distention, that portion of the substance which loses it must successively contract, while the portion which gains it will in the same degree expand. The actual transfer of heat through any mass will hence give occasion to a connected series of minute internal contractions and expansions. To consider the subject more fully, we shall suppose the conducting substance to be, 1. a solid; 2. a liquid; and, 3. a gaseous fluid.

Propagation of heat;

1. When the surplus heat is conducted through a solid substance, a sort of alternating vermicular motion is excited along the whole train of communication. If heat were left to the energy of its own replusion, it would, like light, dart with a speed almost instantaneous. But the time consumed by those interior oscillatory movements retards immensely the rate of transmission. The quickness of the oscillations themselves depends on the elasticity of the conducting substance; but their energy and extent are proportioned to the extreme difference of temperature, and the shortness of the tract, modified essentially by the peculiar nature of the conducting substance. In equal circumstances, glass transmits heat faster than wood, and metal faster than glass. But, even in the same class of conductors, the effects are very different; thus, box delivers the impressions of heat more quickly than cork, and silver conveys them with greater rapidity than platinum.

1. Through solids;

2. When the conducting substance is a liquid. The ordinary transmission of heat through a solid is now greatly augmented, from the diffusion occasioned by the mobility of the affected portions of the medium. Below the freezing point, ice will conduct heat through its substance; but after it has melted into water, a new and powerful agency

2. Through liquids

Climate.

is brought into play. The liquid particles, as they become successively warmer, acquire a corresponding expansion, and, therefore, rise upwards and spread through the mass, *carrying* with them and dispersing the heat which they have received. This diffuse buoyancy will depend evidently on the dilatable quality of the liquid. It is greater in alcohol than in water, and in water than in mercury; it is even more active in hot than in cold water. Near the point of congelation, indeed, the joint conducting power of water is scarcely superior to that of mere ice. The actual flow of a liquid, by whatever cause it is produced, must evidently accelerate the dissipation of heat.

3. Through gaseous fluids;

3. When the medium of transmission is a gaseous substance, the heat is partly still conducted through the substance of the communicating mass, as if this were solid, and partly transferred by the streaming of the corpuscles, which come to be successively affected. But a new principle seems here to combine its influence, and the rate of dispersion in aeriform media is found to depend chiefly on the nature of the mere heated surface. From a metallic surface the heat is feebly emitted; but from a surface of glass, or still better, from one of paper, it is discharged with profusion. If two equal hollow balls of thin bright silver, one of them entirely uncovered, and the other closely enveloped in a coat of cambric, be filled with water slightly warmed, and then suspended in a close room, the former will only lose 11 parts of heat in the same time that the latter will dissipate 20 parts. Of this expenditure 10 parts from each of the balls is communicated in the ordinary way, by the slow recession of the proximate particles of air as they come to be successively heated. The rest of the heat, consisting of 1 part from the naked metallic surface, and of 10 from the cased surface, is propagated through the same medium, but with a certain diffusive rapidity, which in a moment shoots its influence to a distance, after a mode altogether peculiar to the gaseous fluids.

But those effects are modified by the different proximity of the air to the metallic surface. If the silver ball be covered with the thinnest film of gold-beater's skin, which exceeds not the 3000th part of an inch in thickness, the power of dispersion will be augmented from 1 to 7; if another pellicle be added, there will be a further increase of this power from 7 to 9; and so repeatedly growing, till after the application of five coats, when the repellent energy will reach its extreme limit, or the measure of 10.

The approximation of the metallic substratum thus evidently diminishes the power of the external pellicle in darting heat. No absolute contact exists in nature; but air must approach to a boundary of pellicle, or cambric, much nearer than to a surface of metal, from which it is always divided by an interval of more than the 500th part of an inch. A vitreous surface has very nearly the same property as one of cambric or paper: from its closer proximity to the recipient medium, it imparts its heat more copiously and energetically than a surface of metal in the same condition.

Performed by tremulous pulses.

By what process the several portions of heat thus delivered to the atmosphere shoot through the fluid mass, it seems more difficult to conceive. They are not transported by the streaming of the heated air, for they suffer no derangement from the most violent agitation of their medium. The air must, therefore, without changing its place, disseminate the impressions it receives of heat by a sort of undulatory commotion, or a series of alternating pulsations, like those by which it transmits the impulse of sound. The portion of air next the hot surface, suddenly acquiring heat from its vicinity, expands proportionally, and begins the chain of pulsations. In again contracting, this aerial shell surrenders its surplus heat to the one immediately before it, now in the act of expansion; and thus the tide of heat rolls onwards, and spreads itself on all sides.

But these pulsations are not propagated with equal intensity in all directions. They are most powerful in the perpendicular to the projecting surface, and diminish as they deviate from that axis in the ratio of the sine of the angle of obliquity.

Climate.

Nor are the vibratory impressions strictly darted in radiating lines, but each successive pulse, as in the case of sound, presses to gain an equal diffusion. Different obstructions may hence cause the undulations of heat to deflect considerably from their course. Thus, if a cornucopia, formed of pasteboard, present its wide mouth to a fire, a strong heat will, in spite of the gradual inflection of the tube, be concentrated at its narrow end; in the same way, probably, as waves flowing from an open bay into a narrow harbour, now contracted and bent aside, yet without being reflected, rise into furious billows.

But the same pulsatory system will enable the atmosphere to transmit likewise the impressions of cold. The shell of air adjacent to a frigid surface, becoming suddenly chilled, suffers a corresponding contraction, which must excite a concatenated train of pulsations. This contraction is followed by an immediate expansion, which withdraws a portion of heat from the next succeeding shell, itself now in the act of contracting; and the tide of apparent cold, or rather of deficient heat, shoots forwards with diffusive sweep.

That quality which enables a surface to propel the hot or cold pulses likewise fits it under circumstances to receive their impressions. If a vitreous or varnished surface emits heat most copiously, it will also, when opposed to the tide, arrest with entire efficacy the affluent wave; and if, on the other hand, a surface of metal sparingly parts with its own heat, it detains only a small share of each warm appulse, and reflects all the rest.

Pyroscope

Hence the construction of the *Pyroscope*, a delicate and valuable instrument, adapted to measure the warm pulses of air, or the intensity of the heat that darts continually from a fire into a room, which has been vaguely and inaccurately termed *radiant heat*. It is in fact only a modification of the *differential thermometer*, one of the balls being completely gilt with a thick gold or silver leaf. The *pyroscope* being placed at some distance from the fire, the hot pulses are mostly thrown back from the bright metallic surface; but on the naked glass ball they produce their full impression; and the same instrument will serve equally to indicate the pulsations excited from a cold surface. Thus, in a warm apartment, the pyroscope placed before a mass of snow, a block of ice, or even a pitcher of water from the fountain, will quickly intimate the chilling impressions propagated through the ambient medium. Nor has the brightness of the fire or the glare of the snow any sensible influence to affect the result; for, of the small portion of light transmitted, what falls on the diaphanous ball passes almost without obstruction, and what strikes the gilt ball, especially if this be covered with silver leaf, is nearly all reflected.

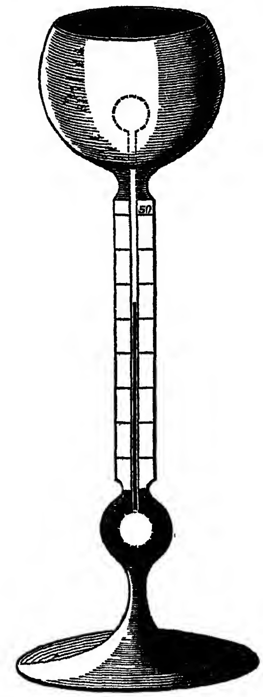
But the pyroscope, in its simple form, is scarcely calculated for making nice observations, when exposed out of doors to the agitation of winds and the effulgence of light. A greater share of this light will generally be detained by the gilt surface than what is absorbed in its passage through the diaphanous ball. On the other hand, all the effects on the instrument will be diminished by the rapidity of the circulation of the air.

Æthrioscope described.

The requisite adaptation is attained by adapting the pyroscope to the cavity of a polished metallic cup of rather an oblong spheroidal shape, the axis, having a vertical position, being occupied by the sentient ball, while the section of a horizontal plane passing through the upper forms the orifice. The cup may be made of thin brass or silver, either hammered or cast, and then turned and polished on a lathe; the diameter being from two to four inches, and the ec-

Climate.

centricity of the elliptical figure varied within certain limits according to circumstances. The most convenient proportion, however, is to have this eccentricity equal to half the transverse axis, and, consequently, to place the focus at the third part of the whole height of the cavity, the diameter of the sentient ball being likewise nearly the third part of that of the orifice of the cup.



The æthrioscope might be reduced to a compact form, having the lower ball encased by a hollow sphere of brass, composed of two pieces which screw together, while the upper ball occupies the focus of the cup, which needs scarcely be more than two inches wide.

This instrument, exposed to the open air in clear weather, will at all times, both during the day and the night, indicate an impression of cold shot downwards from the higher regions. Yet the effect varies exceedingly. It is greatest while the sky has the pure azure hue; it diminishes fast as the atmosphere becomes loaded with spreading clouds; and it is almost extinguished when low fogs settle upon the surface. The name Æthrioscope (from Αιθριος, *serenus, sudus, frigidus*) may, therefore, be justly appropriate to this new combination of the pyroscope. The sensibility of the instrument is very striking, for the liquor incessantly falls and rises in the stem with every passing cloud. But the cause of its variations does not always appear so obvious. Under a fine blue sky, the *æthrioscope* will sometimes indicate a cold of 50 millesimal degrees; yet on other days, when the air seems equally bright, the effect is hardly 30°. Particular winds at different altitudes seem to modify the result, and so perhaps may the transition from summer to winter. The pressure of hygrometric moisture in the air probably affects the indications of the instrument.

On replacing the metallic lid, the effect is entirely extinguished, and the fluid in the stem of the differential thermometer sinks to zero. A cover of pasteboard has at first precisely the same influence; but after it has itself become chilled by this exposure, it produces a small secondary action on the sentient ball, scarcely exceeding, however, the tenth part of the naked impression. A lid of glass or of mica intercepts the impressions like one of paper; for the admission of light has no deranging effect if the æthrioscope be rightly constructed and highly polished. The minute secondary action is almost extinguished, if screens of paper, glass, or mica, be held at some distance above the mouth of the instrument.

The climate of any region is greatly modified by the moisture or dryness of its atmosphere. This has an important influence on its vegetable productions. The modes and instruments employed in estimating this quality of the atmosphere are detailed under the articles Hygrometry and Physical Geography.

The quantity of rain which falls periodically in different countries has great influence on climate. As a general fact, the annual quantity of rain decreases from the equator towards the poles. It is greatest among mountains; but diminishes as we ascend lofty ridges, as the Andes or the Himalayas. For the instruments employed in determining this circumstance, and the inferences deduced from observation, see Physical Geography.

For the effect of climate on the geographic distribution of plants, see Botany, Part iii., where the subject is treated as fully as our limits admit. (J. L.) (T. S. T.)
